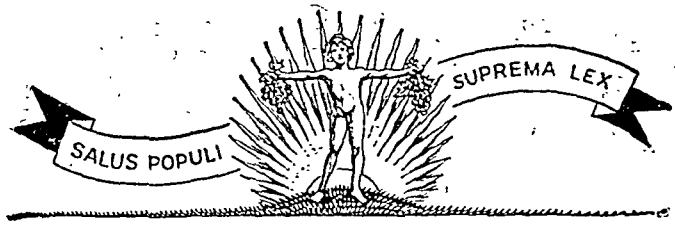
R. B. LLOYD, L. E. NAPIER, and S. N. PAUL (*Indian Journ. of Med. Research*, April, 1929, p. 1056) discuss the serological control of the treatment of kala-azar and add some observations on the significance of hypoproteinaemia; twenty-one graphs showing the behaviour of the serum protein fractions in varying types of the disease treated in different ways support the view originally put forward by Lloyd, in a publication of eight graphs showing the effect of a concentrated course of treatment by Bayer 693 B (para-amino-phenyl stibinate of diethylamine), that these changes may be used as a serological control leading to greater precision in treatment and clearly determining the point of cure. The authors studied the effects (i) of concentrated courses of 693 B consisting of eight daily intravenous injections to a total of 2.3 grams, (ii) of alternate daily injections, (iii) of intramuscular and (iv) of interrupted intravenous courses, (v) of stiburea, and (vi) of sodium antimonium tartrate. The protein graph test was found to be much more sensitive than all other tests, showing at any stage the progress towards cure; it was noted that the serum proteins resumed their normal values approximately 120 days from the commencement of treatment, and several patients were cured by giving fractional courses under the guidance of the graphs. The onset of the second stage is much more rapid with the concentrated courses of 693 B than with any other method of treatment, and its appearance indicates that the final stage of cure has commenced and that the prognosis is good. The authors are of opinion that the speed of onset of the second stage may be regarded as an index of the potency of the treatment, and that by this means the relative efficacy of different drugs and plans of treatment may be estimated. It appears that hypoproteinaemia, the characteristic feature of which is marked reduction in the albumin, produces conditions in which the malaria parasite will exist and reproduce, but that if kala-azar supervenes the reaction of the body produces the high globulin condition which is inimical to the malarial parasite. Apart from their applications to treatment the graphs are valuable as indicating the type of response to be expected when high globulin conditions are treated with the appropriate remedy.

303. The Induction of Tar Tumours in Mice.

I. BERENBLUM (*Journ. Path. and Bact.*, July, 1929, p. 425) describes a series of investigations which were undertaken to discover whether the skin of mice subjected to repeated applications of mild irritants (known to produce hyperaemia) would react more readily than normal skin to a carcinogenic tar, by developing tumours at an earlier date. The first irritant used, repeated freezing with carbon dioxide snow, gave inconclusive results, as the snow itself produced tumours, and also because the tar spread beyond the frozen area, thus complicating the results. A very dilute solution of dichloroethyl sulphide (mustard gas) was then chosen, and these results are now reported. Three groups, each comprising forty mice, were treated as follows: one group received applications of tar containing 0.1 per cent. mustard gas over a small area of skin; another group received applications of tar alone; and the third a 0.1 per cent. solution of mustard gas in acetone alone. It was found that the addition of the 0.1 per cent. of mustard gas to a carcinogenic tar inhibited the tar from inducing tumours, and that the induction of warts is still inhibited if the mustard gas is added to the tar as late as the eleventh week of tarring. This anticarcinogenic effect of mustard gas is due to its action on the animal, so that the skin no longer responds to the tar. In view of these observations Berenblum assumes that if a tar or other mixture of chemicals is found unable to produce tumours when painted on susceptible animals, it contains no carcinogenic principles. One possibility is that no such principle is present, but another possibility is that, though present, it cannot produce tumours because some other substance is also present which causes the skin to become refractory (as mustard gas would do). Some constituents of a non-carcinogenic tar might be absent in carcinogenic tars, and have the property of inhibiting the induction of warts. No such agent may exist (other than in the form of mustard gas), but its non-existence must be proved before ignoring the possibility of such an agent existing.

304. Typhoid Allergy.

J. F. DELALANDE (*Thèse de Paris*, 1929, *No.* 54) applies the term "typhoid allergy" to the various modes of reaction to the typhoid antigen observed in patients suffering from enteric fever. They appear to be due to a systemic intolerance to the proteins contained in the typhoid bacillus. The sensitiveness acquired in enteric fever may be demonstrated by application of the antigen to the conjunctiva (ophthalmo-reaction), or preferably by cuti or intradermal reactions. The author has employed a solution of globulins extracted from typhoid or paratyphoid bacilli and submitted to the prolonged action of formol. This product, while possessing a ver[illegible] toxicity, as is shown by [illegible] ents with the intrader[illegible] ..g results.—(1) In 75 per cent. of enteric patients it produces a papular erythema indicating hypersensitiveness of the patient injected. The age of the patient, the duration of the disease, and the occurrence of relapses do not appear to modify the results obtained. On the other hand, the reaction is absent or very slight in severe attacks of the ataxo-adynamic form. The reactions persist with the same intensity in convalescence and several years after recovery, thus showing that the immunity conferred by the infection is associated with hypersensitiveness of the organism to the typhoid antigen. The allergic state of typhoid patients in the acute stage or in convalescence can also be shown by intramuscular injection of antigen, which causes local tenderness and a rise of temperature of varying duration. (2) In 70 per cent. of healthy subjects the intradermal inoculation of typhoid antigen does not result in any appreciable reaction, while in 30 per cent. it gives rise to a slight redness or a distinct papule like that seen in the typhoid patient. This sensitiveness has hitherto been attributed to a typhoid carrier state or to previous unrecognized typhoid infection. This interpretation, however, is probably applicable to only a small number of cases, and a more likely explanation is a co-sensitization produced by saprophytic or pathogenic intestinal micro-organisms.



DIET AND CONSTIPATION.

THOUGH in all cases of intestinal atony the diet should be carefully considered, it has recently been pointed out by a distinguished physician attached to our largest hospital that "*in spite of the general belief, not very much can be done by diet in the treatment of constipation; and the patient's mind should be disabused of the idea that there is any particular harm in taking a regular aperient, provided it is of the right kind.*"

It can confidently be claimed that Eno's "Fruit Salt" comes within this category, for it is an aperient which acts solely by retaining water in the bowel—as a result of its increased osmotic density—thus maintaining bulk and adequate pressure, and so promoting peristalsis.

In contradistinction to most aperients, Eno's "Fruit Salt" has no irritant or chemical effect on the mucous membrane—and accordingly produces no nausea or discomfort.

"The Doctor's Emergency Reminder."

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy or Household size as required). "THE DOCTOR'S EMERGENCY REMINDER" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

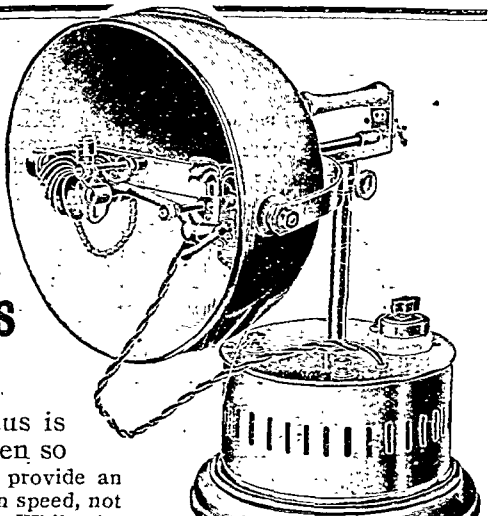
"MEDISUN"

ULTRA-VIOLET LIGHT APPARATUS

100% BRITISH.



Specification:

The "MEDISUN" Ultra-Violet Light Apparatus is of the quartz mercury vapour type. It has been so designed as to eliminate all unnecessary expense, and yet provide an efficient source of ultra-violet radiation, quick in its reaction speed, not requiring adjustment, and foolproof in its mechanical details. Whilst the price of the "Medisun" is quite low, its appearance is really first class. Manufactured in polished aluminium throughout, it does not require frequent cleaning, is designed to stand on any table, weighs only 14 lb., and is a thoroughly reliable piece of apparatus.

RUNNING COST: **30 TREATMENTS 3d.**

Price:
For use on Direct Current ... £12
For use on Alternating Current £18

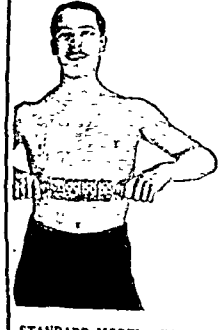
The PUNKT-ROLLER

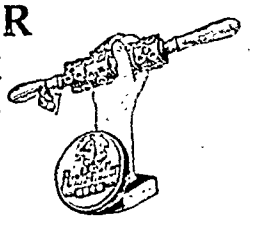


with extra soft rubber suction cups.

"Punkt-Roller." *the Self-Massage Apparatus*
English Patent and 22 Foreign Patents.

The benefits of massage are well-known, but self-massage with the Punkt-Roller is even more beneficial.

Therapeutical use: Rheumatism, Gout, Muscular cramp, adipose tissue, disorders of the circulation, constipation and all metabolic diseases.



The Punkt-Roller possesses 60 removable rubber suction cups. Massage sets up a pressure and suction action, thereby driving the blood to the smallest veins.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.
FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

Motherwell.
September 26th, 1929.

A. G. STEWART,
Town Clerk.

ROYAL NAVAL DENTAL SERVICE.

The Admiralty is prepared to receive applications from qualified Dental Surgeons for entry into the Royal Navy as DENTAL OFFICERS.

Two vacancies are to be filled. Candidates must be below 28 years of age on December 31st, 1929 (unless granted an allowance for age, not exceeding six months, in respect of a period served in a recognized Civil Hospital appointment), and must be registered under the Dentists Act as qualified to practise as Dental Surgeons in Great Britain and Ireland. They will be required to appear before a Selection Committee and to pass a medical examination by a Board of Naval Medical Officers as to their physical fitness for entry.

The Regulations for entry and the forms to be filled up by candidates can be obtained on application to the Medical Director-General of the Navy, Queen Anne's Chambers, Tothill Street, London, S.W.1.

The form of application, accompanied by the necessary documents, must reach the Medical Director-General not later than November 18th.

Lindsey (Lines) County Council.

APPOINTMENT OF LADY ASSISTANT MEDICAL OFFICER.

Applications are invited for the post of Lady Assistant Medical Officer under the Lindsey County Council. Applicants will be required, under the general supervision of the County Medical Officer of Health, to undertake duties in connexion with the Maternity and Child Welfare Service of the Council, including the conduct of Infant Welfare Centres and Ante-natal Clinics and the treatment by modern methods of Venereal Diseases in Women, and also the treatment of errors of refraction in school children and any other duties that may from time to time be prescribed by the County Council.

Salary £500 per annum, rising by annual increments of £15 to £700. Travelling allowance according to the Council's scale (person appointed finding own car).

Applications, which must be on the prescribed form, to be obtained from the undersigned, must be received not later than October 31st, 1929.

W. S. H. CAMPBELL,
County Medical Officer.

County Offices,
Newland, Lincoln.
September 18th, 1929.

County Borough of Bootle.

ASSISTANT SCHOOL MEDICAL OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH.

Particulars of the duties (which include School Medical Inspection and the conduct of Maternity and Child Welfare Clinics) and forms of application may be obtained from the Medical Officer of Health, Town Hall, Bootle.

Applications, accompanied by copies only of not more than three testimonials, endorsed "Assistant Medical Officer," must be returned to me on or before October 19th.

Canvassing, either directly or indirectly, will disqualify candidates.

Town Hall,
Bootle.
September 27th, 1929.

J. SPENCER TUMILTY,
Town Clerk.

Parish of St. Pancras.

GUARDIANS OF THE POOR.

The Guardians of the Poor of the Parish of St. Pancras invite applications from duly qualified candidates for the appointment of a THIRD ASSISTANT MEDICAL OFFICER of the HIGHGATE HOSPITAL, Dartmouth Park Hill, N.19, with salary at the rate of £350 per annum, together with rations, lodging, and laundry, subject to deductions under the provisions of the Poor Law Officers Superannuation Act, 1896.

Candidates must be registered medical practitioners, qualified by law to practise both Medicine and Surgery in England and Wales, and preference will be given to candidates with Institutional experience.

For details as to duties, hours, and off-duty time apply to the Medical Superintendent of the Highgate Hospital.

Applications to be made *on forms* to be obtained from the Medical Superintendent at the Hospital, and selected candidates will be informed when and where they may attend a meeting of the Guardians.

Town Hall,
Pancras Road,
London, N.W.1.
September 24th, 1929.

B. CHAPMAN,
Clerk to the Guardians.

Birmingham Union.

SELLY OAK HOSPITAL.

RESIDENT PHYSICIAN (Male).

Applications are invited for the above post, giving age, full details of experience and qualifications and accompanied by copies of not more than three recent testimonials. Applications should be forwarded so as to reach the undersigned not later than Wednesday, October 9th.

Candidates must hold the degree of Doctor of Medicine of one of the Universities of the United Kingdom, or be a Fellow or a Member of the Royal College of Physicians of London or Edinburgh.

The Resident Medical Staff, including the Medical Superintendent, numbers eight.

The present Hospital accommodation consists of 540 beds for acute cases, divided into general medical, general surgical, gynæcological, obstetrical, and children's sections. Out-patient and Casualty Departments, as well as the following fully equipped special departments, are attached to the Hospital:—Pathological, X-ray, Electro-therapeutic, Massage, Ultra-violet ray.

The admissions and discharges for the year 1928 were 7,284 and 7,448 respectively.

The person appointed must devote the whole of his time to the duties of the office. He will act under the control and direction of the Medical Superintendent and will carry out such duties as may be assigned to him by such officer with the consent of the Guardians. Should occasion arise, the successful applicant must be prepared to assist at any of the other Institutions in the Union without additional remuneration.

The commencing salary will be fixed between £400 and £600, according to qualifications and experience. If fixed lower than the latter figure, the salary will rise to that figure by £50 annually, subject to satisfactory service. The Guardians' regulations provide that at the expiration of 12 months' satisfactory service additional allowances not exceeding in all £150 per annum are granted to the holders of certain prescribed degrees and/or diplomas.

Furnished quarters, rations, laundry, and attendance, will be provided. A deduction of 2 per cent. will be made from the salary and value of the emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896.

Further particulars may be obtained, if desired, on application to the Medical Superintendent, R. P. S. Kelman, Esq., M.B., F.R.C.S (Eng. & Edin.).

Union Offices, Edmund Street, Birmingham.
C. P. BEECH, Clerk to the Guardians.

Hospital of St. Cross, Rugby.

(114 Beds.)

Applications are invited for the posts of SENIOR and JUNIOR RESIDENT MEDICAL OFFICERS (males).

Candidates must be registered medical practitioners, and must be prepared to begin duties as soon as possible. Salary for the Senior post at the rate of £150 per year, Junior at the rate of £100 per year, with board and residence in the Hospital.

Candidates are requested to state whether they are prepared to accept the post of Junior if not selected for the Senior office.

The appointments are for a period of six months only; at the end of that time the Junior will be eligible to apply for the Senior post, which then becomes vacant.

This Hospital is recognized by the University of London for the purposes of the M.D. and M.S.

Applications, stating age and qualifications, with copies of three recent testimonials, should be sent to me immediately.

W. COCKBURN, Supt. & Secretary.

Borough Mental Hospital,

ROWDITCH, DERBY.

CASUALTY OFFICER (Male).

Applications are invited from fully qualified medical practitioners for the appointment of Casualty Officer (male) at the Selly Oak Hospital, Birmingham.

The present Hospital accommodation is 550 beds, divided into General Medical, General Surgical, Gynæcological, Obstetrical, Children and Infectious sections. There is a completely equipped Pathological Laboratory, also X-Ray, Electro-therapeutic, Massage, and Sunlight Departments. Over 2,500 operations are performed annually.

The appointment will be for a period of six months in the first instance, but may be extended at the end of that time.

The gentleman appointed will be required to assist at operations, administer anæsthetics, and undertake casualty work, and such other duties as may be assigned to him by the Medical Superintendent, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salary attached to the appointment is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1895, and for this purpose the emoluments are valued at £200 per annum.

Further particulars of the appointment may be obtained from the Medical Superintendent, Mr. R. P. S. Kelman, M.B., F.R.C.S.(Eng. & Edin.), at the Selly Oak Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than Thursday, October 17th.

Union Offices, Edmund Street, Birmingham.
C. P. BEECH, Clerk to the Guardians.

September 25th, 1929.

Birmingham Union.

DUDLEY ROAD HOSPITAL.

JUNIOR ASSISTANT MEDICAL OFFICERS (Male).

Applications are invited from fully qualified medical practitioners for appointments as Junior Assistant Medical Officers (male) at the Dudley Road Hospital by the Guardians' Medical, Surgical, Maternity, Gynæcological, and Obstetrical Section. There are completely equipped Pathological and Biochemical Laboratories, X-ray, Electrical, Massage, Sunlight, and Dental Departments. Approximately 5,000 operations are performed annually.

The appointments will be for a period of six months in the first instance, but may be extended at the end of that period.

The persons appointed will be required to assist at operations, to administer anæsthetics, and undertake casualty work and such other duties as may be assigned to them by the Chief Medical Officer, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salaries attached to the appointments will be at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salaries and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum. Fourteen days' leave will be granted to the successful candidates during their term of office.

Further particulars of the appointments may be obtained from the Chief Medical Officer, F. W. Ellis, Esq., M.D., F.R.C.S., Dudley Road Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded so as to reach me not later than Wednesday, October 9th.

Union Offices, Birmingham.

GEORGE WATTS, Secretary-Supt.

County Borough of Darlington.

APPOINTMENT OF DEPUTY MEDICAL OFFICER OF HEALTH.

The Town Council invite applications from qualified persons for the post of Deputy Medical Officer of Health at a salary of £750 per annum.

The appointment will be a whole-time one and be terminable at any time by three months' notice on either side, and the person appointed will be required to act under the control and direction of the Medical Officer of Health and to carry out such duties as the Council or the Medical Officer of Health may assign to him from time to time.

He will be required to undertake the treatment of all persons attending the Council's Venereal Diseases Treatment Centre and to act as an Assistant School Medical Officer and as a Medical Certifier under the Mental Deficiency Acts, 1913 to 1927.

The appointment will be subject to the approval of the Ministry of Health and the Board of Education.

The person appointed must live in Darlington, must not engage in private practice, and will be required to pass a medical examination, and the appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Applications on forms to be obtained from the undersigned, together with copies of three recent testimonials, must be received by him on or before noon on October 23rd.

Canvassing will disqualify.

Town Clerk's Office, Houndgate, Darlington. September 27th, 1929.
H. HOPKINS, Town Clerk.

Parish of Bermondsey.

ASSISTANT MEDICAL OFFICER (RESIDENT).

The Guardians of the Parish of Bermondsey invite applications from duly qualified medical gentlemen for the appointment of Assistant Medical Officer at their Hospital, Lower Road, Rotherhithe, London, S.E.16.

Candidates must have had at least twelve months' experience in hospital after registration, and should have enough surgical experience to be able to undertake emergency operations.

The appointment will be made for a period of six months only in the first instance, renewable for a further period upon satisfactory service.

Salary at the rate of £400 per annum for the first six months, increasing to the rate of £450 per annum for the second six months, together with rations, furnished apartments, washing, and attendance. The person appointed will be required to devote his whole time to the service of the Guardians, reside in the hospital, and act under the direction of the Medical Superintendent.

The hospital contains 687 beds.

The appointment is subject to the sanction of the Ministry of Health and the provisions of the Poor Law Officers' Superannuation Act, 1896.

Applications ... to be, qualifications, and date of three recent testimonials, and places to be made on forms to be obtained from the undersigned.

Applications must be returned to me at the latest by 10 a.m. on Monday, October 14th, and selected candidates will have notice when to attend a meeting of the Guardians.

Canvassing, either directly or indirectly, will disqualify.

By Order,
Guardians' Offices, 283, Tooley St., London, S.E.1
HENRY H. REEVE, Clerk to the Guardians.

St. John's Hospital, Lewisham, S.E.13.

Applications are invited for the resident appointments of MALE CASUALTY OFFICER and MALE HOUSE PHYSICIAN. These appointments are tenable for three or six months, commencing on November 1st, at a salary of £100 p.a. on November 1st, at a salary of £100 p.a. Applications, with copies of testimonials, should reach the Secretary at the Hospital not later than October 14th.

Birmingham Union.

SELLY OAK HOSPITAL.

RESIDENT PHYSICIAN (Male).

Applications are invited for the above post, giving age, full details of experience and qualifications and accompanied by copies of not more than three recent testimonials. Applications should be forwarded so as to reach the undersigned not later than Wednesday, October 9th.

Candidates must hold the degree of Doctor of Medicine of one of the Universities of the United Kingdom, or be a Fellow or a Member of the Royal College of Physicians of London or Edinburgh.

The Resident Medical Staff, including the Medical Superintendent, numbers eight.

The present Hospital accommodation consists of 540 beds for acute cases, divided into general medical, general surgical, gynæcological, obstetrical, and children's sections. Out-patient and Casualty Departments, as well as the following fully equipped special departments, are attached to the Hospital:—Pathological, X-ray, Electro-therapeutic, Massage, Ultra-violet ray.

The admissions and discharges for the year 1928 were 7,284 and 7,448 respectively.

The person appointed must devote the whole of his time to the duties of the office. He will act under the control and direction of the Medical Superintendent and will carry out such duties as may be assigned to him by such officer with the consent of the Guardians. Should occasion arise, the successful applicant must be prepared to assist at any of the other Institutions in the Union without additional remuneration.

The commencing salary will be fixed between £400 and £600, according to qualifications and experience. If fixed lower than the latter figure, the salary will rise to that figure by £50 annually, subject to satisfactory service. The Guardians' regulations provide that at the expiration of 12 months' satisfactory service additional allowances not exceeding in all £150 per annum are granted to the holders of certain prescribed degrees and/or diplomas.

Furnished quarters, rations, laundry, and attendance, will be provided. A deduction of 2 per cent. will be made from the salary and value of the emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896.

Further particulars may be obtained, if desired, on application to the Medical Superintendent, R. P. S. Kelman, Esq., M.B., F.R.C.S.(Eng. & Edin.).

C. P. BEECH,
Clerk to the Guardians.

Union Offices,

West London Hospital,
Hammersmith, W.6.

An HONORARY REGISTRAR is required for the Throat, Nose, and Ear Department. The appointment is for one year from November 1st, and subject to annual re-election, may be extended for a period not longer than three years. Applicants must be duly qualified registered medical practitioners.

Applications, accompanied by copies of testimonials, must reach me not later than first post on Thursday, October 17th. Candidates must attend the Meeting of the Medical Council on Friday, October 18th at 4 p.m., and prior to that date call upon and send copies of application and testimonials to each Member thereof. They must not canvass Members of the Board, but nevertheless must send a copy of their application and testimonials to each Member thereof, and if notified be in attendance at a Meeting of the Board at 5 p.m. on Tuesday, October 22nd, when the appointment will be made.

H. A. MADGE, Secretary.

West London Hospital,
Hammersmith, W.6. (225 Beds.)

Required, One NON-RESIDENT HOUSE OFFICER (part-time) for Children's Department for six months from November 1st next, subject to one month's notice on either side. Applicants may be male or female. Salary at the rate of £150 per annum. Candidates must be registered under the Medical Act and have held a resident appointment at a Children's Hospital or in the Children's Department of a General Hospital.

Applications and copies of testimonials in quadruplicate (which must be made on printed forms obtained from me) must reach me not later than first post on Friday, October 11th. Selected candidates will be required to call upon such members of the Medical Staff as directed, to be in attendance at a Meeting of the Medical Council on Friday, October 18th, at 4 p.m. and the House Committee Meeting at 4.45 p.m. the same day when the appointment will be made.

H. A. MADGE, Secretary.

West London Hospital,
Hammersmith Road, W.6.

One SENIOR ASSISTANT MEDICAL OFFICER and Three JUNIOR ASSISTANT MEDICAL OFFICERS will shortly be required for work in the Venereal Diseases Department. Salaries: Senior £450 per annum, Juniors £350 per annum each. The appointments will be subject to six months' notice on either side. Candidates must be registered medical practitioners who have had special experience in the diagnosis and modern treatment of venereal diseases.

Applications, accompanied by copies of testimonials, must reach me not later than first post on Tuesday, October 22nd. Candidates must attend a Meeting of the Medical Council on Friday, October 25th, at 4 p.m., and prior to that date call upon such members as directed, and send copies of application and testimonials to each member thereof. The appointments will be made by the House Committee at 4.45 p.m. the same day. Further details with regard to the duties can be obtained from the undersigned.

H. A. MADGE, Secretary.

MR. HERBERT NEEDES,

31, Bedford Street, Strand, W.C.2.
(Temple Bar 3873.) —— (Estab. 1860.)

This Agency (the oldest in the Kingdom) undertakes the SALE of PRACTICES and PARTNERSHIPS, AUDITS, and VALUATIONS, and the SUPPLY OF LOCUMS and ASSISTANTS.

No Charge to Purchasers. All Business receives Mr. NEEDES' personal attention.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair 1732, 1733

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

5. MIDDLESEX.—RESIDENTIAL SUBURB.—PARTNERSHIP.—A one-third share is offered in a very sound good mixed-class Practice, averaging over £3,200 p.a., including panel of 1,600. Fees 3/6 upwards. Very suitable house, with nice garden, can be rented on lease at £100 p.a. Up-to-date Cottage Hospital, which is being enlarged. Premium 2 years' purchase. University Graduate having held Hospital appointments preferred.
6. HERTS. — Better-class Country PRACTICE, within easy reach of London. Old-established, and patients are chiefly of the professional c[illegible] Average income £1,000 p.a., including panel of 480 and about £6[illegible] from appointments. Advice and medicine 3/6 to 10/6, visits 3/6 to 21/-. Not much midwifery. Exceptionally nice house, with every modern convenience and half an acre of garden. Price for freehold £2,700. Excellent spot, society, and schools. Prem. £1,500.
7. MIDLANDS.—In a clean thriving Hospital town (pop. 130,000), an old-established mixed-class PRACTICE worth last year £1,100, including panel producing over £400 p.a. and £150 from Public Medical Service. Large house, with ample accommodation, good garage, garden, etc. Vendor's leasehold having 31 years unexpired (ground rent £9 16s.). Price £1,500. Premium £1,650.
8. WILTS.—COUNTRY PRACTICE, on outskirts of large town. Well-established and producing for the immediate past year over £1,630, including panel of 1,590. Advice and medicine 3/6, visits 5/- upwards. Detached double-fronted house, with good garden. Garage. Rent on lease £60 p.a. Premium £2,400.
9. NEW ZEALAND (South Island).—In a delightful and popular seaside resort (pop.; town over 17,000 and country 5,000, greatly augmented by visitors) on main line, a well-estab. PRACTICE averaging £1,816 p.a. for the past 5 years, including about £175 from Lodges. Consultations fees 10/6. Mids. 4 to 10 gns. (75 cases p.a.). House is situated in excellent position and contains 14 rooms, with 1/2 an acre of garden, tennis court, etc. Can be leased. Excellent educational facilities. Sport of all kinds.
10. LONDON, S.W.—Within easy reach of Charing Cross.—Very old-established middle-class non-panel PRACTICE averaging over £2,000 p.a. Fees 2/6 to 10/6. Mids. 3 to 10 gns. (about 12 cases). Commodious house, with 2 reception, 5 bedrooms, etc. Garden. Rent on lease £65. Premium £3,100.
11. HOME COUNTY.—Within 40 miles of London.—Good Country PRACTICE, established over 100 years, in very attractive district within 10 miles of favourite County Town. Patients include many county families. Income for immediate past year nearly £1,400, including transferable appts. worth about £120, and panel of 750, producing with mileage £470. Fees from 2/- to 21/-. Little midwifery. Excellent house, with 3 reception, 5 bedrooms, etc. Good garden. Garage. Rented on lease at £80 p.a. Premium £2,200.
12. CORNWALL.—FAVOURITE COAST TOWN.—PARTNERSHIP.—A one-third share is offered in a well-established Practice, having good surgical scope. Average gross cash receipts £4,200 p.a. Panel of about 1,800 and good appts. Very nice house available on rental, or smaller house or rooms could be taken. Hospital and prospect of appt. on staff. Premium £2,400.
13. PARTNERSHIP.—SOUTH-EAST COAST.—A one-third share (with increase later) is offered in a well-established non-dispensing Practice situated in a popular residential town and health resort. Receipts for past three years average over £3,000, with good scope. Fees from 5/- to 21/-. Very little mid. Attractive house, with 4 reception, 6 bedrooms, etc. Garden. Garage. Premium 2 years' purchase.
14. SOUTH-WEST OF ENGLAND.—SEAPORT TOWN.—PARTNERSHIP.—A one-sixth share is offered in a very old-estab. sound mixed-class Practice situated in residential outlying suburb. Average gross cash receipts for past three years over £6,700, including panel of 4,000, and appts. worth about £750. Excellent house, property of retiring partner, can be bought; or purchaser can select his own residence. Good sport and schools. Premium 2 years' purchase.
15. CARDIFF.—Old-established better-class non-dispensing worth last year about £1,400. Panel of 450. Fees from 5/- to 21/-. Very little midwifery. Good house in best part of the city. Can be rented on lease. Premium £2,000.
16. ESSEX.—Rapidly developing outlying suburb, within ten miles of the Bank.—Well established and increasing PRACTICE. Income last year £2,274. Panel of 1,646. Fees 2/6 upwards. Very little midwifery, but large scope. Very good corner house, in excellent repair, with 2 reception, 5 bedrooms, separate professional rooms, etc. Electric light. Garden. Garage. Price for freehold £1,550. Prem. £3,600.
17. PARTNERSHIP.—WILTS.—A two-fifths share, with increase up to one-half later, is offered in a good mixed Practice situated in a pleasant town, with country surroundings. Income from share £900 p.a. Good scope for increase, particularly in surgery and midwifery. Cottage Hospital. Premium 2 years' purchase.
18. WITHIN 50 MILES OF LONDON.—Well-established and increasing PRACTICE situated in small country town in very pretty district. Income last year over £800, including panel of over 500, and appts. worth about £60. Visits 3/6 to 21/-, medicine extra. Exceptionally nice house can be bought, or smaller house available, which can be rented at £50 p.a. Good schools for boys. Premium 1½ years' purchase. Good scope for increase.
19. BORDERS OF WARWICK AND OXON, — Old-established Country PRACTICE, in attractive district near two good towns. Average income for past three years £1,157, including panel of 580 and appts. worth over £100. Fees 2/6 to 21/-. Good house, with 2 sitting, 4 bedrooms, etc. Separate entrance to surgery. Garden. Garage. Price for freehold £1,250. Hunting, golf, and schools within reach. Premium 1½ years' purchase.
20. SHROPSHIRE.—Unopposed Country PRACTICE, in pretty district, producing this year at the rate of about £1,400, including panel of 550, and appts. worth £65. Visits 3/6 to 7/6, with medicine and mileage extra. Midwifery from 3 gns. About 20 cases. Suitable house, with modern conveniences, and containing 3 reception, 5 bedrooms, etc. Electric light. Garden. Garage. Rent on lease £100 p.a. Good sport and schools. Premium £1,500.
21. YORKS.—LARGE TOWN.—Old-established mainly working-class PRACTICE. Income £1,250. Panel of over 1,400. Fees 2/6 to 5/-. Well-situated house, with good garden. Price £1,500. Prem. £1,500.
22. LIVERPOOL.—Centrally situated old-established PRACTICE. Income about £1,500. Panel of over 2,500, worked from Branch Surgery. Visits and medicine from 3/6 to 7/6. Little midwifery. Large corner house, with garden and garage. Recently redecorated. Electric light and new hot water system throughout. Price, freehold, £2,000. Large scope for increase. Premium 1½ years' purchase.
23. SUSSEX.—VILLAGE PRACTICE in delightful surroundings, at present producing over £1,150 p.a., but capable of considerable increase. Fees from 3/6 upwards. Exceptionally charming residence standing in 2½ acres of well laid out garden, and containing lounge hall, 2 reception, 7 bedrooms (3 fitted with h. and c. water basins), dressing room with fitted bath, and other usual offices. Central heating. Electric light. Garage for 2 or 3 cars. Price for freehold £4,500. Premium £1,700.
24. SOUTH-WEST OF ENGLAND.—HOSPITAL TOWN.—PARTNERSHIP.—A half share is for disposal in a good middle-class non-panel, general, and surgical Practice, averaging for the past three years over £5,000 p.a. Good house, with 2 reception, 6 bedrooms, etc. Premium 2 years' purchase. Purchaser should hold the F.R.C.S.
25. HANTS.—COUNTRY PRACTICE, at present producing about £480 p.a., but offering large scope. Panel of 280. Fees 3/6 to 10/6. Mid. from 3 gns. Convenient house, with 2 reception, 5 bedrooms, etc. Garden and garage. Can be rented on lease at £75 p.a. Premium £500 for prompt sale.
26. NORTH-WEST LONDON.—Within easy reach of Charing Cross.—Old-established mixed-class PRACTICE averaging over £2,000 p.a., including panel of about 1,400. Fees 2/6 to 10/6. Midwifery 3 to 15 gns. Six-roomed house, with bathroom, kitchen, etc. Rent on lease £85. Surgery premises (part let off) rented at £75 p.a. Could be worked as "lock-up." Premium 1½ years' purchase.
27. SOMERSET.—Increasing PRACTICE, situated in very pretty district. Income last year over £900, with good scope. Panel of nearly 400, and appts. worth about £250. Fees 2/6 to 15/-. Not much midwifery. From 7 to 15 gns. Good house, with 2 reception, 5 bedrooms, etc. Garden. Price for freehold £1,275, part on mortgage. Excellent sport. Schools. Premium 1½ years' purchase.
28. GLOS.—LARGE TOWN.—PARTNERSHIP.—A half share of an old established good-class non-dispensing Practice, owing to retirement through ill health of senior partner. Income about £5,000, with small select panel. Fees 5/- to 10/6. Purchaser should be about 40, married, and keen on midwifery. Good house available at low rental. Premium 2 years' purchase part by instalments.
29. LIVERPOOL.—Mixed-class PRACTICE, producing this year at the rate of over £1,200. Panel of 560. Good house, specially built and well situated, containing 2 reception, 4 bedrooms, etc. Large garden. Garage. Price for leasehold £1,700, part on mortgage. Prem. £1,550.
30. ASSISTANTS REQUIRED.—(1) Wilts.—Indoor £300 p.a. or more if experienced in Surgery. (2) Beds.—Outdoor £450 p.a. (3) Herts.—Outdoor £450. Scotch Graduate having the M.R.C.P. (4) Kent.—Indoor £300 p.a., with increase later. (5) London, S.E.—Indoor £250 p.a. Time for reading. (6) London, S.E.—Indoor £300 p.a.

Full Schedule of Terms and Conditions will be forwarded on application.

HORMOTONE
for
PREMATURE SENILITY
and
OLD AGE

Stimulates metabolism
Increases muscle tonicity
Raises respiratory exchange
Effects marked subjective improvement

"Old age being caused by degeneration of the endocrine glands, especially the thyroid and sexual glands, all that is necessary to secure rejuvenation is to improve the condition of these glands. The best and easiest way to do this is to administer by the mouth extracts of these glands, after their extirpation from healthy animals. . . . .

"The persons treated looked considerably younger after it, to the extent of ten or fifteen years, and sometimes even more. The wrinkles in the face already began to disappear four or five weeks after the treatment, and, at the same time, previously corpulent persons, losing their excess of fat, were made to look slender, thus imparting a youthful impression."

(Lorand, "Life Shortening Habits and Rejuvenation," 1922.)

DOSE: 1 or 2 tablets three times daily.

FRANK COOPER'S

OXFORD MARMALADE

will be exhibited on

STAND 62

London Medical Exhibition

By appointment. *By appointment.*

A One-pound Jar of Cooper's "Oxford" Marmalade will be sent free to any medical practitioner on request.

FRANK COOPER LTD.
VICTORIA WORKS, OXFORD

Certificate of the International Institute of Physiology and Hygiene states:

"This marmalade is prepared from the highly esteemed Seville orange and pure sugar. It represents a table commodity of the highest possible dietetic value and scientific skill in manufacture. It is entirely free from added colouring or flavouring bodies, and contains no injurious preservative material. It presents the delicate and slightly bitter flavour so much appreciated in home-made marmalade, and possesses stimulating and gustatory properties of a high order. The use of such marmalade as the kind under consideration is highly beneficial, for it promotes a healthy appetite and a natural flow of the digestive juices, and acts generally as a tonic to the stomach and liver."

British Medical Journal.

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

A NEW WORK

CHRISTOPHER'S

JUST ISSUED

MINOR SURGERY

"Christopher" is something entirely new in the field of books on Minor Surgery, confining itself strictly to the subject, presenting more detailed technique, and offering a far greater number of illustrations that really visualize the technique described in the text. It can be said with confidence that "Christopher" is the newest, most complete, best illustrated, and most thoroughly practical and usable book on minor surgery in the language.

Octavo of 694 pages, with 465 illustrations. By FREDERICK CHRISTOPHER, M.D., F.A.C.S., Associate in Surgery at Northwestern University Medical School. With a Foreword by ALLEN B. KANAVEL, M.D., F.A.C.S., Professor of Surgery, Northwestern University Medical School. Cloth, 36s. net.

Granger's Physical Therapeutic Technique

NEW

One of the outstanding features of the book is the "Index of Diseases." This section of 140 pages lists diseases and conditions alphabetically and under each gives the physical therapeutic method or methods likely to be most beneficial. Indications and frequency of the treatment, the technique, dosage, etc., are given and there are numerous illustrations to demonstrate the instruction of the text.

Octavo volume of 417 pages, illustrated. By FRANK B. GRANGER, M.D., late Physician in Chief for Physical Therapy at the Boston City Hospital. Cloth, 36s. net.

Mellish-Wilson's Writing of Medical Papers

THIRD EDITION

This book will aid medical writers to prepare their manuscripts in order to convey information with brevity, accuracy, and clearness. It includes chapters on words in good usage, italics, punctuation, pitfalls in diction, case histories, chapter, paragraph and sentence, references, revision, manuscripts, marking corrections, etc.

By MAUD H. MELLISH-WILSON, Editor of The Mayo Clinic Publications. 12mo. of 184 pages. Cloth, 7s. 6d. net.

Willius' Electrocardiograms

A MAYO CLINIC MONOGRAPH

This is a brand new book—a new volume in the "Mayo Clinic Monographs." The entire book is devoted to the reading, to the interpretation of the records themselves and to the clinical significance of the findings. The 368 illustrations are clearly explained by detailed legends which in themselves comprise a complete text and frequently give the required help without reference to the text.

Quarto volume of 219 pages, with 368 electrocardiograms. By FREDERICK A. WILLIUS, B.S., M.D., M.S. in Medicine, Section on Cardiology, The Mayo Clinic, Rochester, Minn.; and Associate Professor of Medicine, The Mayo Foundation, University of Minnesota. Cloth, 35s. net.

Wechsler on the Neuroses

NEW

This book is unusually rich in diagnostic helps. Psychiatric facts are emphasized in a chapter on differential diagnosis. Attention is drawn sharply to the organic, neurologic and other medical conditions that might lead to diagnostic errors. There is a concise chapter on taking a psychiatric and neurologic history and on making a mental examination. Full technique is given for making tests.

Octavo of 330 pages. By ISRAEL S. WECHSLER, M.D., Associate Professor of Clinical Neurology, Columbia University, New York City. Cloth, 18s. net

W. B. SAUNDERS COMPANY Ltd. 9, Henrietta Street, LONDON, W.C.2

From EDWARD ARNOLD & CO.'s List.

To be Published on OCTOBER 31st.

Principles of Bacteriology and Immunity

By W. W. C. TOPLEY, M.A., B.Ch., M.R.C.S., F.R.C.P., Professor of Bacteriology and Immunology, and G. S. WILSON, M.D., B.S., D.P.H., Reader in Bacteriology and Immunology, in the London School of Hygiene and Tropical Medicine. Two Volumes, about 1,500 pages, with 240 Illustrations. 50s. net.

Text-Book of Pathology.

By ROBERT MUIR, M.A., M.D., Sc.D., F.R.S., Professor of Pathology in the University of Glasgow. New Second Edition, enlarged. viii + 872 pages, 501 Illustrations. 35s. net.

A Manual of Pharmacology

By W. E. DIXON, M.A., M.D., B.Sc., F.R.S., Examiner in Pharmacology in the Universities of London, Oxford, and Cambridge. New Seventh Edition, nearly ready. xii + 486 pages, 97 Illustrations. 18s. net.

The Methods of Clinical Diagnosis

By A. G. GIBSON, M.D., F.R.C.P., Lecturer in Morbid Anatomy in the University; and W. T. COLLIER, M.D., M.R.C.P., Honorary Assistant Physician to the Radcliffe Infirmary, Oxford. viii + 398 pages, 136 diagrams and 4 coloured plates. 12s. 6d. net.

Lectures on Diseases of Children

By ROBERT HUTCHISON, M.D., F.R.C.P., Physician to the London Hospital and to the Hospital for Sick Children. Great Ormond Street. Fifth Edition. xii + 460 pages, 87 Illustrations. 21s. net.

Practical Physiology

By Professor E. P. CATHCART, F.R.S., University of Glasgow; Professor D. N. PATON, F.R.S., University of Glasgow; and Professor M. S. PEMBREY, F.R.S., University of London. New Third Edition. Ready October 17th. xvi + 408 pages, 206 Illustrations. 18s. net.

A Text-Book of Physiology

By H. E. ROAF, D.Sc., M.R.C.S., L.R.C.P., Professor of Physiology, London Hospital Medical College. viii + 606 pages. 325 Illus. 25s. net.

The Practice of Surgery

By RUSSELL HOWARD, C.B.E., M.S.Lond., F.R.C.S.Eng., Surgeon to the London Hospital, Lecturer on Surgery, London Hospital Medical College. Third Edition. viii + 1,280 pages. 8 coloured plates and 523 Illustrations. 30s. net.

The House-Surgeon's Vade-Mecum

By RUSSELL HOWARD, and ALAN C. PERRY, M.B., M.S., F.R.C.S., Assistant Surgeon to the London Hospital. Second Edition. viii + 520 pages, 159 Illustrations. 12s. 6d. net.

LONDON: EDWARD ARNOLD & CO., 41 & 43, MADDOX STREET, W.1.

SECOND EDITION. 674 Illustrations. Two Volumes. 28s., postage 1s. 3d.

THE SCIENCE AND PRACTICE OF SURGERY

By W. H. C. ROMANIS, F.R.C.S., and P. H. MITCHINER, F.R.C.S., Teachers of Surgery, St. Thomas's Hosp.

"A well-balanced account of the Science and Art of Surgery as practised at the present day. . . . A student preparing for a pass examination in Surgery need not buy a number of books dealing with its different branches. If he absorbs the information contained within the covers of these volumes he will certainly satisfy the examiners, and will, moreover, have acquired a very good basis of knowledge for higher degrees in Surgery. . . the authors are to be congratulated . . . a very useful and practical manual for the undergraduate student. The price is very moderate."—THE LANCET.

SEVENTH EDITION. 900 Illustrations (43 in Colour). Two Volumes. 70s. postage 1s. 3d.

ROWLANDS & TURNER'S OPERATIONS OF SURGERY

"This is probably the most important modern text book on Operative Surgery published by British Surgeons.

"The volumes are not only safe as a book of reference, but of the greatest value to the general surgeon. The searching and detailed revision which has been carried out in the last edition does great credit to the ability and industry of the authors."—PRACTITIONER.

NOW READY. 3s. 6d., postage 3d.

Table in Horizontal Position with Head Piece lowered. Note the length of Head Piece and extreme angle to which this can be lowered.

An ACHIEVEMENT in SCIENTIFIC CONSTRUCTION

"Emesay Popular" Model OPERATING TABLE

£45 100% BRITISH

ESSENTIALLY similar in design to our well-known "Universal" Model. By the experience gained in its manufacture, and the use of modern methods of production, we are able to offer a first-class heavy and stable Table at a price within the reach of the smaller Hospitals and Nursing Homes.

Its range of movements makes it suitable for any operation required by Modern Surgery.

The perfection of its design has been proved by the unqualified commendation expressed by users of the original model of which the Popular Model is an offspring.

CONTRIBUTES ALL THAT A TABLE CAN CONTRIBUTE TO A SUCCESSFUL OPERATION

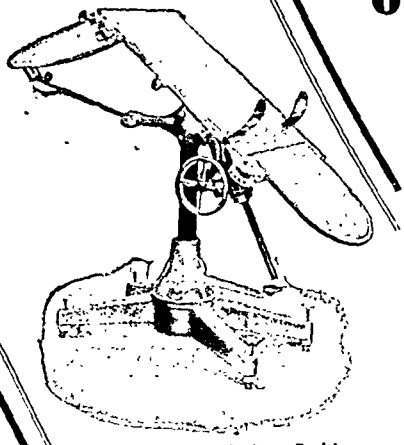

Table in Trendelenburg Position. Both throughout the movement and after the desired position has been obtained, table is held absolutely secure. Foot Piece automatically falls into position shown

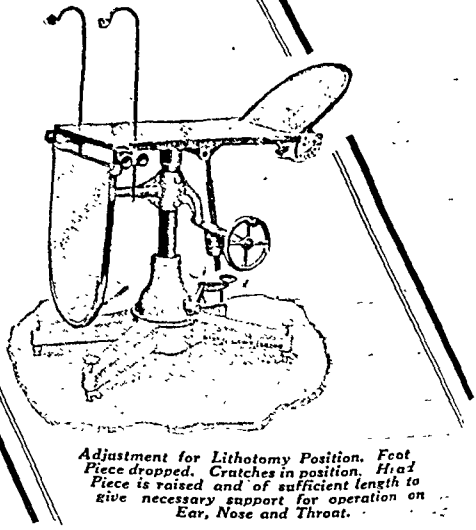
Some Hospitals where our "Universal" Model is in use—

St. Thomas's Hospital; Royal Free Hospital; City of London Chest Hospital; Hull Royal Infirmary; Aukland General Hospital; Maude Memorial Hospital; Crown Agents for the Colonies; India Office.



Adjustment for Lithotomy Position. Foot Piece dropped. Crutches in position. Head Piece is raised and of sufficient length to give necessary support for operation on Ear, Nose and Throat.

"EMESAY POPULAR"

Heavy Oil-pump Base. Shoulder Rests, Lithotomy Stirrups.

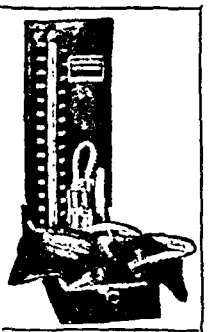
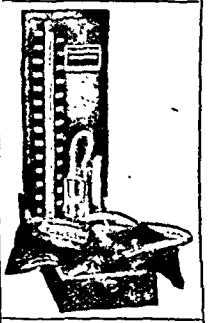
SPECIALIZATION in this one field of endeavor—bloodpressure apparatus—has enabled us to attain in the *Lifetime Baumanometer,* the highest degree of *Accuracy—Simplicity—Permanence—Beauty*—the four chief essentials of modern bloodpressure instruments. Under these headings we list the many innovations and refinements that insure these in faithful performance to Baumanometer owners.



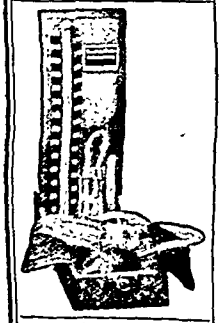
Scientific Accuracy

Every *Lifetime* Baumanometer is individually calibrated, scientifically accurate and GUARANTEED to remain so—accurately interchangeable glass Cartridge Tube and standardized steel reservoir—stabilized mercury column—no oscillations—no mercury spilling—minimum oxidation—readily cleanable tube and reservoir—calibrations directly on tube, white background for mercury—most easily read scale and tube and *a full unobstructed scale reading from 0 to 260 or 300 mm.—no parallax errors. A master instrument!*



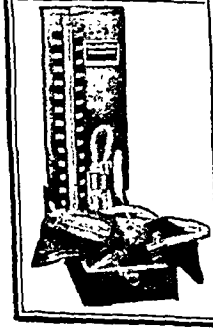
Utmost Simplicity

Instantly ready for use—no adjustments, attachments, or fitting several parts together—one compact, EASILY PORTABLE unit—positive control over mercury column—equally practical for desk or out side use. *The essence of simplicity!*



Real Permanence

Glass Cartridge Tube GUARANTEED AGAINST BREAKAGE FOR YOUR LIFETIME (a written guarantee is given to every purchaser)—entire manometer unit encased in metal and *chromium-plated*—no cemented joints—no friction points—nothing to get out of order—nothing to wear out except pure gum tubing and bag and English handmade pure gum Baumanometer bulb which will last for years. *A truly lifetime apparatus!*



Well-Proportioned Beauty

Hand-rubbed solid walnut case—beautiful ivoroid scale—the result of years of specialized endeavor to perfect an instrument of correct proportion, design, and construction. *A beautiful and modern piece of equipment!*

You Couldn't Expect More—

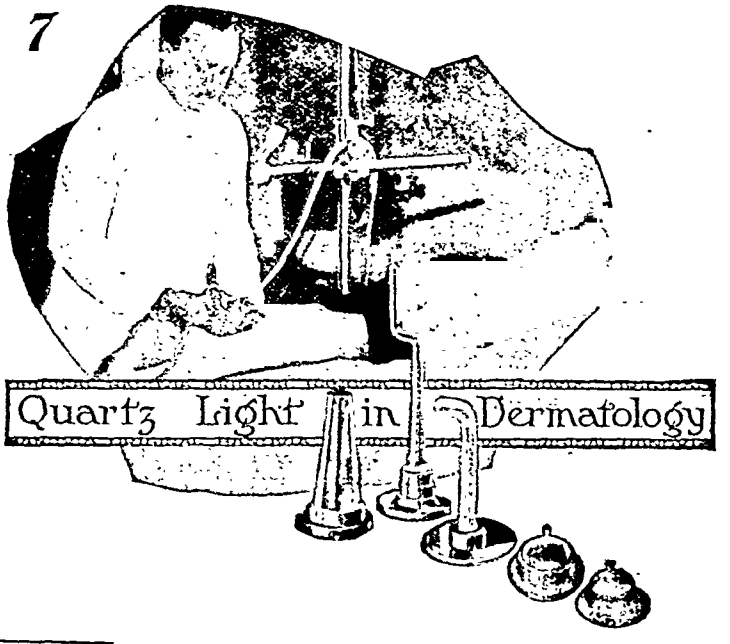
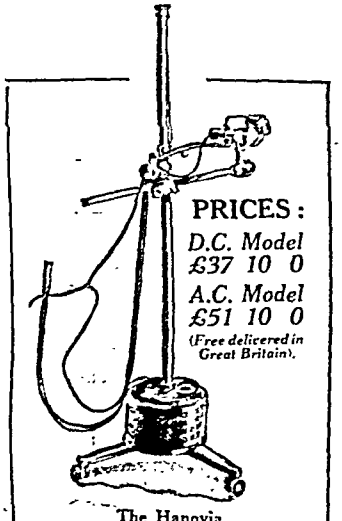
Practitioners' Problems

Number 7





The Hanovia KROMAYER LAMP.

Varicose Ulcers

"A series of cases of varicose ulcers of the leg was treated in 1926-7. Moderately good results were obtained by employing the ordinary Bach air-cooled Mercury-Vapour Quartz Lamp; whereas radiation by means of the water-cooled Kromayer Lamp, using pressure, or at a distance of 1 to 4 inches for 2 to 5 minutes, generally gave a completely successful result. A feature of the Ultra-Violet Ray treatment was the almost immediate relief or diminution of pain."

Intestinal Disinfection

ALIMENTARY TOXÆMIAS

PUTREFACTIVE bacteria increase in numbers in the intestine as age advances. They are relatively scanty in the young child, but after middle life are usually present in considerable numbers. Of the micro-organisms concerned, proteolytic anærobes are probably the most important.

In individuals with a normal intestine and free evacuations, they may do little harm, but in those subject to intestinal catarrh, these putrefactive bacteria become more numerous and active, their products are formed in greater quantity and are more freely absorbed, and the condition of alimentary toxæmia results. The manifestations of this state are very protean, *e.g.*, "rheumatic" conditions, digestive upset, neurasthenia and neuralgias, increased blood pressure and its complications, and many others. The treatment, in the first place, obviously should be *intestinal disinfection*. For this purpose nothing surpasses the use of KEROL CAPSULES. They have solved for years the question of disinfection of the alimentary tract. They definitely reduce the bacterial content of the intestine, as shown by the reduction in *B. coli* by 99% when the capsules are regularly administered for a period of from seven to ten days.

We have from time to time published several booklets containing clinical evidence as to their value, and these we will gladly forward, on receipt of a postcard, to any member of the Medical Profession.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Rational Alkaline Medication

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

must be adapted to the physiological requirements of the human organism, in order to neutralize excess acid products and restore alkaline balance, without the risk of intoxication.
A trial will promptly convince you of the value of Alka-Zane as antacid, diuretic, and to restore normal alkalinity, in gouty and rheumatic conditions, gastric or intestinal hyperacidity, and in certain skin diseases.

ALKA-ZANE

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated "Alocol" is the preferred form of treatment. Its advantages over the usual oxides and alkalis are manifest. Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition. Consequently such remedies are contraindicated, especially in stubborn, chronic cases.

The action of "Alocol" is superior in every way, because it does not merely confine itself to combating the symptoms of the trouble, but attacks the origin itself.

"Alocol" fixes the acid, not by neutralization, but by adsorption. It relieves pain, is slightly astringent, and limits the acid secretions. "Alocol" is always well borne; no harmful secondary action follows its administration, and its therapeutic effect is not diminished with prolonged use.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request

PLEASANTER FOR PATIENT—

MORE CONVENIENT FOR YOU—

For internal examination, manual or instrumental, K-Y Jelly gives the freest lubrication. It flows readily, cannot bind, and is quickly and conveniently squeezed out of its tube in exactly the quantity required. It does not soil clothing and is easily removed from hands or instruments by rinsing them in water.

K-Y Jelly is a blend of certain vegetable substances with carefully balanced proportions of boric acid, and does not interfere with the application of local remedies.

Physicians and Surgeons are invited to write for samples to *Dept. B*, Johnson & Johnson (Gt. Britain) Ltd., Slough, Bucks, stating the name of their local supply house.

* * *

K-Y Lubricating Jelly is obtainable from medical supply houses and pharmacists throughout the world. Tubes in cartons, 1/3 (Hospital size, 2/6).

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Therapeutic Ointments

Ung. Renaglandin and Ung. Renaglandin Anæsthetic	Invaluable in Hæmorrhoids—Styptic.
Ozoline	An ideal method of employing the detergent action of Hydrogen Peroxide.
Ung. Iodsam	A stainless ointment containing 10 % of Iodine. Useful in Rheumatic affections, Tinea, and Ringworm.
Ung. Zoleas	A combination of Zinc and Mercury Oleates: Invaluable in dry and chronic Eczema, especially of gouty origin.

HANDFORTH LABORATORIES, CLAPHAM ROAD, LONDON, S.W.9.

"A SENSE OF INCREASED FITNESS"

"I have now been prescribing Bemax in my practice for well over a year, and I think it only right to let you know that I am very well satisfied with the results obtained. There is no doubt, in my opinion, that the regular addition of Bemax to the diet (even of apparently healthy individuals) leads to a sense of increased fitness and better general health. I have proved this by personal experience as well as observation on and statements from others. As regards pathological cases, I have found it particularly useful in Dyspepsia and Chronic Constipation." M.B., Ch.B., D.P.H.

Bemax is now established as the B vitamin food. Over 34,000 members of the medical profession in Great Britain have applied for Bemax for personal trial. The diseases for which medical men are prescribing Bemax are Constipation, Intestinal Toxæmia, Debility, Neurasthenia, Rheumatism, Gastric disturbances, and all forms of skin disease. In fact, any ailment due to B-vitamin deficiency. If you have not tried Bemax, a free full-size tin will be sent you on receipt of your professional card.

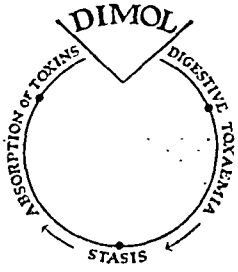
Break the Vicious Circle in Chronic Constipation



THOUGH THE differential action of many of the toxins of the intestinal tract on the tissues of the body is still a matter of conjecture, it is probable that each putrefactive organism creates a toxin productive of some deleterious effect. It is on this hypothesis that constipation is primarily ascribed to the influence of some of these poisons acting directly on the musculature of the bowel or on the nerve cells and ganglia in its walls.

HOWEVER THE diminished peristaltic action is caused, it is certain that it is the beginning of a vicious circle, which is completed by a deepening line of inertia, stasis, digestive toxæmia, and lowered resistance of the glands and cells of the mucosa.

TO BREAK THE vicious circle, an efficient, non-toxic intestinal disinfectant is clearly indicated; the resultant action is easy to understand. Now that the problem of intestinal disinfection has been solved by the introduction of the benzene derivative Dimol, we know that the putrefactive organisms can be destroyed, thus shutting off the further supply of toxin. The nerve cells, released from the paralysing action of the toxins, are once more free to stimulate the muscles, with the consequent result that peristalsis is re-established—the accumulated contents of the intestine are expelled and the vicious circle is broken.

Samples and Literature will be sent on application to the

Dimol Laboratories, 40, Ludgate Hill, London, E.C.4.

Pituitary
(Posterior Lobe)
Extract
B.D.H.

A genuine *British* product

Issued also in boxes containing 100 ampoules specially for hospital use

With the advance of endocrine treatment, and with the consequent wider use in medicine of organo-therapeutic products, it has become a matter of particular urgency for the physician to employ only those products which he knows to be thoroughly reliable; it is not feasible in actual practice for the physician himself to test the relative potencies of different preparations—he must confine the material in his armamentarium to that issued by manufacturers whose products are known to be of an unassailably high standard. Pituitary (Posterior Lobe) Extract B.D.H. comes within this category, and physicians employing it can do so with full confidence. It is doubly standardised for the pressor action and for the effect in contracting uterine muscle.

VISIT OUR STAND (No. 120) at the LONDON MEDICAL EXHIBITION, OCTOBER 14th—18th

Boots Pure Drug Co., Ltd., Nottingham.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

Health Aspects of Vita-Weat

In cases of diet regime a readily acceptable and beneficial alternative to ordinary bread will be found in Vita-Weat—the whole-wheat British crispbread.

The "Lancet's" Report.

Being made from 100% stone-ground whole wheat, Vita-Weat preserves all the vitamins intact. The *Lancet* reports that Vita-Weat is "a valuable foodstuff, more particularly in respect of its content of Vitamin B." Vita-Weat is also rich in Vitamins A and D, in proteins, and in the valuable mineral salts so necessary to health.

Extremely Palatable.

Vita-Weat is extremely palatable, possessing a delicious "crunchiness" and ripe-corn flavour. Its crispness encourages mastication and so promotes a healthy condition of the teeth and gums.

High Calorie Value.

"The calorie value of Vita-Weat," says the *Practitioner*, "is 2,132 per lb., which may be compared with the calorie value of fresh white bread, namely 1,210 per lb." It will thus be seen that Vita-Weat possesses a high physiological fuel value.

To Counteract Constipation.

The branny scales of Vita-Weat act as a stimulant to normal peristalsis, whilst not exerting an undue irritative effect on the intestinal mucous membrane.

To Prevent Obesity.

The starch granules in Vita-Weat are thoroughly disintegrated. No starch passes unconverted into the body to cause obesity and indigestion. Vita-Weat is "completely assimilable," states a report of the Royal Institute of Public Health.

The Standard of Purity of

INSULIN "A.B." Brand

TRADE A B MARK

The ideal Insulin should be so pure that its use is entirely free from any untoward effect. This is the aim of the makers of Insulin "A.B.", who have adopted their own stringently high standard of purity and have always maintained it. Reductions in their prices have never involved the slightest sacrifice of quality.

Insulin "A.B." is so pure—and therefore so free from reaction-producing proteins—that the number of clinical units per milligram of substance approaches the maximum possible, i.e., the equivalent of crystalline Insulin.

The world-wide supremacy of Insulin "A.B." is due to this unequivocal purity no less than to its well-known potency and stability under all conditions.

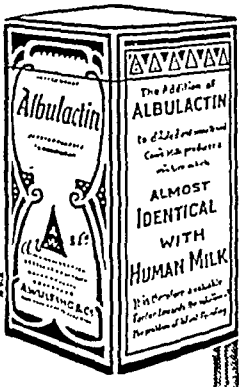
Wulfing Products



The Pale and Weakly Child

Particularly the type in which a definite pathology cannot be demonstrated, generally responds well to calcium therapy in the form of Kalzana. For instance, a recent clinical report states:

"I gave Kalzana to a child with peculiar symptoms of apathy, listlessness, etc. There has been a marked improvement—she sleeps better, and takes her food with some appetite."

The clinical results produced by Kalzana are equally satisfactory in diseases of children amenable to calcium medication, especially in tubercular disease, and the type of malnutrition associated with acute infectious disorders.

Kalzana is a definite chemical combination of calcium-lactate and sodium-lactate in the form of a double salt. The special virtue of the product is due to the action of the sodium in raising the blood alkalinity to the extent necessary to secure the adequate retention of the calcium constituent. Therefore Kalzana therapy means calcium retention. It is used in over 200 British Hospitals and Sanatoria, including many leading Children's Hospitals.

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

THE LIME FOOD

Precision in Infant Feeding

Every requirement needed to provide a correctly balanced infant's food is supplied by properly modified cow's milk and Albulactin. The all-important proteid and lactalbumin percentages are exactly correct, and *always* within the control of the physician; an important consideration when the food has to be adapted to the peculiar digestive capacities of individual infants.

Albulactin is pure lactalbumin—the vital proteid of human milk—supplied in the form of an impalpable powder. It is quite simple to prepare, and may be prescribed with confidence in all cases of artificial feeding, from the premature weakling to the normal healthy infant.

The British Medical Journal says:

"There appears to be every reason to expect this preparation to prove of great value in the 'hand feeding' of infants."

Supplied in bottles at 1/9, 3/6 and 7/-

Albulactin

Made by A. WULFING & CO., Amsterdam, Holland.

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available on special terms. Adequate samples for clinical trial sent with pleasure upon request.

(*Aesculapius*)

MUSCULAR ATONY

It is well known that hypodermic injections of an extract of the posterior lobe of pituitary gland exercise a prompt and well sustained effect on nonstriated muscle. The application of this knowledge makes available a most valuable agent for the treatment of atonic conditions. Post-pituitary extracts have been usefully employed in intestinal paresis, for the control of hæmorrhage, as a general tonic, and also exert specific effects on the musculature of the cardio-vascular system, increasing tone and thereby raising arterial tension. It is a valuable adjunct in dealing with syncope, extreme exhaustion, and shock. Excellent results are obtainable with it in the treatment of pneumonia.

INFUNDIBULIN

This is the extract of the Posterior Lobe of the Pituitary Gland prepared at Evans' Biological Institute. It is standardised so that 1 c.c. contains 10 International Units. In addition to the uses described above, its value in the practice of midwifery is indisputable.

It is available in 1 c.c. and 0.5 c.c. ampoules. Samples on application to

Evans' Biological Institute, Runcorn.

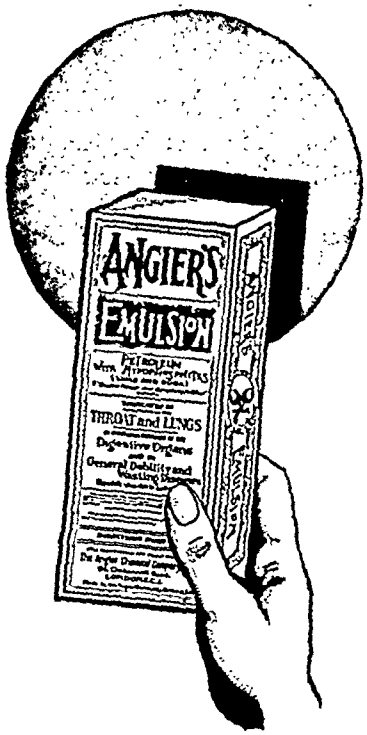
The Emulsion for Children

In many of the wasting diseases of childhood, a sensitive irritable stomach and intestines preclude proper nourishment.

Under the administration of Angier's Emulsion these organs become pacified and retentive, digestion is strengthened, and the assimilation of food is normal and complete. It is oftentimes surprising how quickly pale, flabby, weakly infants and children gain flesh, strength and vitality when they are given the Emulsion systematically.

We confidently urge its trial in marasmus, scrofulosis, inherited tuberculosis, anæmia, and in the malnutrition associated with acute infectious disease. It is likewise one of the most useful and dependable remedies for the treatment of bronchitis, whooping-cough and the respiratory affections associated with measles and scarlet fever.

The pleasant cream-like flavour of Angier's Emulsion and its ready miscibility with milk or water, make it eminently suitable for administration to children.



ANGIER'S EMULSION

Food Poisoning—
The Kaylene Treatment

The following letter has been received recently.

Messrs. Kaylene, Ltd.

Dear Sirs,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him **only** Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

"SMILER"

HEAT TREATMENT of MILK

The unanimous results of recent researches on milk as a food for the Infant have shown that processes which adopt intensive temperature periods, such as are necessarily employed in pasteurisation, the preparation of evaporated milks, and spray process dried milks, have a disturbing influence on the calcium and phosphorus of the milk, and consequently on the retention by the Infant of these important elements. In addition, it has been shown by various investigators that such processes have a destructive effect on essential vitamins.

Cow & Gate Milk Food

Cow's Milk made safe and suitable for Baby

On the other hand, such drying processes—as "Cow & Gate" process, in which the milk is held for a matter of a few seconds at a high temperature—have been shown to be free from the above disturbances, and the full nutritive and vitamin value of the original rich West Country milk is preserved intact.

Made under strictly hygienic conditions and under expert supervision, Cow & Gate is uniform in its outstanding properties, and standard in its composition throughout the year.

The makers will gladly supply samples for clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

COW & GATE Ltd.,

GUILDFORD.

VITAMINS A, B & D
HAVE ALWAYS BEEN IN
CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession — a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

An Address
ON
TUBERCULOSIS IN EARLY CHILDHOOD.*

BY
CHARLES McNEIL, M.A., M.D., F.R.C.P.Ed.,
PHYSICIAN, ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN; LECTURER ON DISEASES OF CHILDREN, EDINBURGH UNIVERSITY.

This discussion was to have been opened by Professor von Pirquet of Vienna, who would have treated the subject with the authority of exceptional knowledge. His death is a loss not only to us on this occasion but also to medicine as a whole. And in deploring the loss, it is fitting that we should also pay tribute to the great and lasting value of his work. We need not attempt now to sum up and appraise the work of von Pirquet, which was not confined to the field of tuberculosis; but in that important field his great contribution was the introduction of the cutaneous *tuberculin test*—the first test of tuberculous infection that was at once safe, accurate, and convenient. The widespread application of the Pirquet test has revealed in the living the prevalence of concealed and apparently innocent tuberculous infection, and has also given us a method of distinguishing tuberculous and non-tuberculous disease. It would be hardly possible for a general discussion of tuberculosis to take place at the present day without a reference to the Pirquet test.

Our subject—tuberculosis in early childhood—is not only wide and complicated, it is also well worn by much previous discussion. He who attempts to discuss it again must run the risk of omitting things that may seem important, and of repeating what has been often said before. But it will be granted that it is an important subject for all those who have the medical care of children; and there may be advantage in reaffirming what is well known and in bringing up for fresh discussion familiar points of dispute.

In the first place let us define as the period of our survey the first five years of life, and compare the amount of tuberculous disease in all its forms at this time with similar succeeding periods. That can be done by taking the total deaths from tuberculosis in England and Wales for 1927. (Chart 1.) The number of deaths in the first period—about 3,000—greatly exceeds that in the later period of

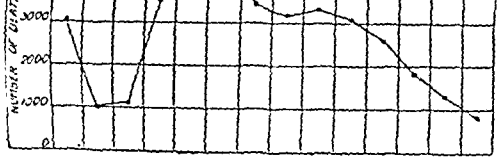

CHART 1.

childhood and of puberty; thereafter in adolescence and throughout the prime of life the figures are about or exceed the 4,000 mark. The first phase of tuberculosis is therefore, as regards fatal disease, easily the most important of the whole period of childhood. But it is worth remembering that in the first period of childhood the number of deaths from tuberculosis is exceeded by those from measles and whooping-cough, and far exceeded by those from diarrhoea, bronchitis, and pneumonia. Further, all these diseases just mentioned, deadly in themselves, are known to facilitate tuberculous infection. Even with these facts in view, tuberculosis in the first five years of life is an important disease, either in relation to tuberculosis at any later period, or in comparison with the other common and fatal diseases of the same period.

* Delivered in opening a discussion in the Section of Diseases of Children at the Annual Meeting of the British Medical Association, Manchester, 1929.

Types of Tuberculous Disease in the First Five Years.

An accurate idea of the relative prevalence of clinical types can again be obtained by examination of the Registrar-General's death figures for England and Wales in 1927. Three are selected—meningeal, respiratory, and abdominal tuberculosis—and their relative incidence in five-yearly periods for the first half of life are shown in Chart 2; together they account for the great majority of deaths from tuberculosis in the period of our survey. Cases of disseminated tuberculosis, which also make a considerable total at this period, are not included; it is probable that the great majority of these deaths are due to a focus of primary disease in the abdomen or thorax. Cases of so-called surgical tuberculosis—glands in the neck and disease of the bones and joints—are also numerous at this period, but these make only a small *contribution to the total of deaths.*

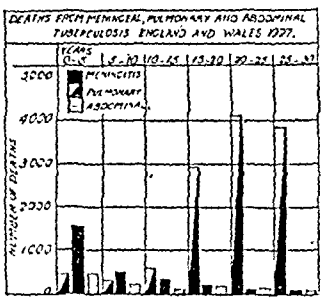

CHART 2.

The chart demonstrates clearly a number of facts. Meningitis easily takes the first place in this list of deaths in the first five years; and the total for this period is far greater than at any subsequent period. Abdominal tuberculosis also causes far more deaths at this period than at any later period. The number of deaths from pulmonary tuberculosis practically equals that from abdominal tuberculosis in the first period; but although it falls in the second five years of childhood, it thereafter rapidly rises, and towers above any other type of tuberculous disease as a cause of death. In the first five years, in England and Wales, the deaths from tuberculous meningitis are three times greater than those from pulmonary and from abdominal tuberculosis. These three types, while they do not constitute the whole of tuberculosis at this period, form the greatest and most important part of it.

I now present a survey of 254 cases of tuberculosis admitted to my ward during the past eight years; they *include non-fatal cases, and their examination, together with* the result of post-mortem examination, will allow a further and more accurate analysis of types of tuberculous disease at this period; some clinical features will also be discussed and some broad conclusions bearing on preventive measures will emerge. They are grouped in age periods: birth to 2 years, 2 to 5 years, and 5 to 12 years.

Tuberculous Meningitis, Pulmonary and Abdominal Tuberculosis.

Age incidence in early and later childhood.

	Birth-2 years.		2-5 years.		Birth-5 years.		5-12 years

The deaths given in the table do not express death rate; an unknown number of cases discharged from hospital must have died later.

A few general remarks may be made before proceeding to some observations on each of these types of tuberculous disease.

The Cutaneous Tuberculin Test.

A brief discussion on the value of the Pirquet test will be suitable here. It is a common remark that the test often fails in tuberculous meningitis and in general

tuberculosis; this has not been my experience in tuberculous children, if the test is properly performed. And in the first two years a positive tuberculin test is of great value in diagnosis and of grave significance, because at this period latent or healed tuberculosis is a rare event and active tuberculosis is generally fatal. In later childhood a positive test is of less value in diagnosis; it only permits a "tuberculous" interpretation of the clinical evidence, but in itself it has not even corroborative value. At the later period of childhood, however, a negative test is of great value in excluding tuberculous disease—although it must be remembered that the test may, although rarely, fail to appear in an actually tuberculous condition.

Latent Tuberculosis.

The existence of healed or dormant tuberculous lesions is an important fact in later childhood and in later life. Do such lesions exist in the first period of life that we are considering; and to what extent? I would offer for discussion the following statement. In the first two years of life tuberculous infection nearly always proceeds to tuberculous disease; and tuberculous disease ends in death in nearly all cases of pulmonary lesions, either by acute pulmonary tuberculosis or by meningitis, and has a like ending in a majority of cases of abdominal tuberculosis. At this period dormant or healed tuberculosis is a rare event; in the third, fourth, and fifth years it becomes more common; while the number of recoveries from active tuberculous disease also increases. In the above table of cases I have excluded a group of latent or dormant tuberculosis, where a condition of ill health seemed to be partly due to a concealed tuberculous focus, in some cases presumed to be in the thorax, in others in the abdomen, but in which no proof of active tuberculous disease could be obtained. The group was a small one, 18 in all; one only was under 2 years of age, while six were from 2 to 5 years, and the remainder above 5 years.

Dr. Agnes Macgregor, the pathologist of the Edinburgh Children's Hospital, has lately been collecting evidence on this question of latent tuberculosis in childhood from post-mortem examinations, and has kindly allowed me to give one or two of her general results. Healed or inactive tuberculous lesions are rare under 2 years; they increase after that age; and the great majority of these healed or latent tuberculous lesions are in the abdominal mesenteric glands.

The practical conclusion of this clinical and post-mortem evidence is that latent tuberculosis can scarcely be said to occur in infancy, and is uncommon in the later years of the period of our survey. And yet our clinical consciences are often troubled by this haunting fear of latent tuberculosis, throughout childhood, and particularly in the lungs. The loose statements frequently made as to the prevalence of latent tuberculous infection in early childhood are not supported either by clinical or post-mortem evidence. The problem of diagnosis at this time is the discovery of active, not of latent, tuberculosis in the thorax or abdomen.

Tuberculous Meningitis.

This type of tuberculous disease, so common and so deadly in the first years of childhood, is only the end-result of an earlier focus of disease implanted in the body; it is a secondary and not a primary type. Without post-mortem examination it is not possible to detect and locate in many cases of meningitis the primary seat of disease; this is certainly true of meningitis in childhood. In the clinical series given above of 91 cases of tuberculous meningitis in children up to 12 years, 73 occurred under 5 years; and of the latter group, this final phase occurred in nearly all without clinical evidence of tuberculous disease elsewhere. Of the total (91), post-mortem examination was made in 51, and the primary lesion was revealed in all but two; so that in the great majority of these it was now possible to re-distribute the cases of meningitis among the two other primary groups of pulmonary and abdominal tuberculosis. The results of this determination of the primary lesion in tuberculous meningitis are shown in the following table.

Primary Lesions in Tuberculous Meningitis.

Age Period.	Pulmonary.	Abdominal.	Cervical Glands.
Birth to 2 years	15	10	1
2 to 5 years	9	4	0
5 to 12 years	11	2	1
Total	33	16	2

In two other necropsies no primary tuberculous lesion was found. The number of cases (53) is perhaps large enough to warrant the general statement that nearly all cases of tuberculous meningitis are derived from a glandular or visceral focus in thorax and abdomen, a clear majority being thoracic, and a smaller number from the abdomen (the number here, no doubt, varying in different areas, according to the amount of bovine infection). It is uncommon for tuberculous meningitis to follow tuberculous glandular disease in throat and neck.

In cases of tuberculous meningitis it is uncommon, even after careful clinical examination of the throat and neck, the thorax and abdomen, to discover during life the seat of the primary focus. Occasionally, however, physical signs of a pulmonary focus may be found, and verified during life by an *x*-ray photograph, and after death at necropsy. The location of the primary focus is the most important thing to be done in any case of tuberculous meningitis; in most cases this essential information can only be obtained by post-mortem examination, and without this knowledge the adoption of preventive measures in the family becomes more difficult. The value of post-mortem examination in tuberculous meningitis can hardly be exaggerated in revealing the situation of the primary focus, and in a majority of cases this is a thoracic lesion.

Pulmonary Tuberculosis.

A few remarks may be made bearing upon the clinical problem of diagnosis. The difficulty of diagnosis is perhaps greater in the period of infancy, the first two years, than later, although it is never easy. In the first two years active pulmonary tuberculosis assumes a greater variety of forms. Four of these may be mentioned: tuberculous bronchitis becoming broncho-pneumonia; acute caseous pneumonia with or without acute cavity formation; chronic fibroid pneumonia with cavities; and a caseous tuberculous process at the hilum of the lung, spreading into it.

The first two, bronchitis and broncho-pneumonia, and massive caseous pneumonia may be discussed together. They occur at an age when simple bronchitis and lobar pneumonia are common conditions, and they give the same physical signs. Some clinical features are helpful in distinguishing the tuberculous conditions: the illness in these is insidious in onset and quiet in its course, and at first there is less dyspnoea and general distress; but presently there is definite weakness, pallor, and loss of flesh. This quiet but relentlessly progressive course is characteristic of the tuberculous process. The *x*-ray picture in tuberculous broncho-pneumonia is, of course, unmistakable. Finally, although there may be little cough and no expectoration, a throat swab will often show tubercle bacilli; and a positive tuberculin cutaneous reaction is also of much value.

As to the third type, even at an early age pulmonary tuberculosis may be a relatively slow process, lasting for many months, and associated with fibroid change and cavity formation. Here diagnosis is easier.

The fourth type, a caseous change in tuberculous glands at the root of the lung and slowly extending inwards, is more difficult to diagnose than any other type. Morbid physical signs may be absent, and at the early stage *x*-ray examination may also be negative. In such a case there are only the general signs of a severe progressive toxaemia.

Tuberculous pleural effusion is an uncommon event in the first two years. In my own clinical series there was not a case at this time; between 2 and 5 years there were three cases.

It is worth repeating again that tuberculous infection of the lung or the mediastinal lymph glands in the early years of life either proceeds to an active and fatal pulmonary tuberculosis or ends in meningitis; very rarely is it arrested as a healed process either in lung or gland.

Abdominal Tuberculosis.

One of the interesting things about this type is the variation in its frequency in different towns and districts of the British Isles; but whatever these local variations are, in all areas the greatest number of deaths falls in the first five years. In Scotland the number of deaths from tuberculous disease of the intestines and peritoneum is relatively much higher than in England. In London there were 16 deaths under 5 years from this condition in 1927; and in Edinburgh, with a tenth of the population, 9 deaths. Throughout Northern England and all Scotland abdominal tuberculosis is still a grave problem. In early childhood primary abdominal tuberculosis is due to infected milk, as also are a large majority of cases of tuberculous glands of the neck and at least a third of cases of tuberculous bones and joints. High rates of mortality and morbidity from abdominal tuberculosis in any area are a reliable index of widespread infection of the milk supply with tubercle bacilli.

PREVENTIVE MEASURES.

It is hardly necessary to emphasize the greater importance of preventive as against curative treatment of tuberculosis at any time of life; and this is certainly true of the first period, where in some of its clinical types the number of deaths equals the number of cases. The greatest impetus towards prevention of tuberculosis has been the conviction of the medical mind that the disease is a contagious one, transmitted from one individual to another, and the gradual persuasion of the body of the people of this truth. Another demonstration, hardly less powerful towards prevention, was that tuberculous disease in cattle can be transmitted by milk to man. It is a curious fact that Laennec and Koch, the two greatest discoverers in the field of tuberculosis, both held wrong views here, Laennec declaring that pulmonary phthisis was not contagious, and Koch that bovine tuberculosis could not be communicated to man.

Tuberculosis in childhood is peculiar in that both these kinds of contagion and transmission are powerfully at work; and this is specially true of the early period of childhood which we are discussing. As medical men we are fully persuaded of this, and we have a fairly accurate knowledge of the various methods and channels of this double transmission to the young child. If the people had the same general persuasion of the existence and danger of this double contagion, the reduction of the disease in young children would become more rapid. As it is, the mortality figures from all kinds of tuberculous disease, which have declined at every period of life, are declared by statisticians to have fallen most of all in the first five years. Education of the people in the fundamental facts is still needed, however, and ought to keep an important place in medical preventive measures. There is still need, not merely for preaching the truth, but also for denouncing error. The old heresy that tuberculosis is a hereditary disease, fatally transmitted from parents to children, still lingers in the minds of many, and blinds them to the real dangers. This propaganda of education, both by the family doctor and by the organized tuberculosis service, has gone on for many years, and has produced its effect; but with an "educated" people, and the means of reaching them so manifold, it should be possible for all to know and understand the simple essential facts of tuberculous disease in children and of its transmission by milk and man.

It is in the first two or three years of life that this twofold attack of tuberculosis is so common and so dangerous. It has been said of syphilis, but it can be said more truly of tuberculosis in early life, that it is shared between the father, the mother, and the children like the daily bread.

Hospital Statistics of Tuberculosis in Children.

The death rates given in the Registrar-General's reports are our main source of information as to the progress or decline of tuberculosis. Other figures that might be expected to give useful information are the statistics of cases and deaths occurring in the principal children's hospitals throughout Great Britain; these, however, are not presented in any uniform way; the totals given are often not of cases, but of admissions. Where cases—for example, of bone tuberculosis—are readmitted several times, it is obvious that the total numbers may give a quite misleading statement of the prevalence of the disease. It is most desirable that children's hospitals should adopt a uniform method of presenting and analysing their statistics of tuberculosis: if this were done a much more accurate and detailed survey of the prevalence and progress of the disease and of its main types in the various hospital areas could be obtained. Such a yearly survey would be of great value, both to the medical profession and to the public health authorities in each area, in stimulating and directing preventive measures.

Tuberculous Milk.

The problem of milk in relation to tuberculosis in young children is complicated. The amount of bovine tuberculosis varies a good deal in different areas, but in a large number of our towns and districts it is very considerable. In these areas the medical profession and the public health authorities are well aware of the prevalence of tuberculous milk, and are now taking more active steps to improve the situation by the provision of tubercle-free milk, better veterinary inspection, and by wholesale pasteurization of milk. It will be a long time before tuberculosis in cattle can be stamped out; in the Manchester report for 1927 the veterinary officer records an increase in the samples of tuberculous milk. Manchester is not alone in this; but in the work of Delépine it has given a lead to other places in exposing the danger by bacteriological examination of milk samples.

The widespread existence of tuberculous milk constitutes the greatest and most serious example of food poisoning in this country, and gives Great Britain a "bad eminence" in this matter over almost every other great State in the Old and New Worlds. And there is no general agreed policy, either national, municipal, or private, to meet this danger. Until all our dairy cattle are free of tubercle there are two ways of dealing with the situation—either that the public health authorities require and supervise the pasteurization of all milk supplies for young children, with the exception of certified milk, or that the medical profession unanimously recommend the boiling in the home of all milk for children. But medical opinion is not agreed as to the necessity for this step; and this division of opinion, which has lately become more marked, is chiefly due to two things. The virtue of freshness in milk, owing to recent knowledge of vitamins, has become emphasized, and unduly so. Also there is a vague but widely held belief that a mild bovine infection is widespread, and is a protective vaccination against the more dangerous human and pulmonary infection, and that although this rough uncontrolled vaccination costs many lives and much crippling disease, the price must be paid as a protection against a greater danger. It is very desirable that the medical profession should reconsider the question of sterilization of milk: we are agreed as to the prevalence of tuberculous milk and of milk-tuberculosis in children; it would be a great gain if we were agreed in recommending the sterilization of all ordinary milk used by young children. It is always hard to change the customs and habits of the people—these household laws that are older and stronger than Acts of Parliament. It is settled custom to boil our eggs; we have far more reason to boil our milk, and it is an easy matter to make good the rather dubious loss of vitamins.

Human Tuberculosis.

Pulmonary tuberculosis, with all its consequences, is not only the greater part of the problem of tuberculosis in young children; it is also the more difficult to deal with. It can be ascribed almost entirely to human infection—that is, to active tuberculosis in the father, mother, or some other individual in close contact with the young child. As we have seen, tuberculous meningitis, which causes the greatest number of deaths in the first five years of life, is in the majority of cases due to pulmonary tuberculosis. In the early years of life the child, carried in its parents' arms and closely attended by them, has that close contact which

readily allows contagion to pass to it; and this condition of nature and necessity mainly explains the height of the tuberculosis curve in the first five years, and its drop in the later years of childhood, when there is increasing freedom and separation.

Efficient prevention of pulmonary tuberculosis in the young child demands, first, the detection of phthisis in the parent or adult relative; next, measures to guard against the danger of their close contact with the child. Even so, notwithstanding all the advantages of a special service and of trained nurses who point out the dangers and how they may be guarded against, the risk of infection of the child in a crowded home must remain high. And in the young child infection is followed by disease with its high mortality. Not seldom it is the appearance of active tuberculosis in the child that gives the clue to the existence of unsuspected phthisis in one or other parent. This is one of the great benefits of notification of all forms of the disease—that from many sides information is gathered that may lead to the detection of cases of adult phthisis. The key to the problem of prevention of pulmonary tuberculosis in childhood lies in the early detection of cases of phthisis in the middle period of life, in their isolation, in their instruction in hygiene, and, above all, in reduction of their numbers. The segregation of young children from tuberculous parents and insanitary homes, as in the Grancher system in France, is not feasible as a general policy; in the few cases where it is practicable it is, of course, the most effective safeguard.

With regard to the children in a family where phthisis in a parent has been discovered and dealt with, what further preventive measures are available? Is it possible to detect and arrest early infections? This is a difficult but important question, and one that receives much attention from tuberculosis officers. In the infant and younger child it seems to me that little can be done here, for latent or dormant infections are very rare, and active disease is nearly always fatal. In abdominal tuberculosis from milk infection the case mortality is lower, and latent abdominal infection, although uncommon, may occur. The occurrence of latent pulmonary infection in the older child, its detection, its relation to phthisis in the adolescent and adult, are all important questions, which, however, lie outside the scope of our subject.

CHRONIC CERVICITIS (LEUCORRHOEA): ETIOLOGY AND SYMPTOMS.*

BY

J. BARRIS, F.R.C.P., F.R.C.S.,

PHYSICIAN ACCOUCHEUR WITH CHARGE OF IN-PATIENTS, ST. BARTHOLOMEW'S HOSPITAL.

Chronic cervicitis (leucorrhoea) forms one of the commonest conditions met with in both hospital and private practice. The discharge is often persistent; not infrequently it is neglected; it is resistant to treatment, and the results of treatment are often disappointing. The condition may, moreover, give rise to complications, not only locally in the pelvis, but also in other parts of the body. Chronic cervicitis is therefore a subject of great practical interest and importance, and is deserving of careful study.

Chronic cervicitis may be defined as an inflammatory affection which involves the mucous membrane of the cervical canal and of the os uteri externum. It is characterized by leucorrhoea and the presence usually, but not invariably, of a cervical erosion. It is due to infection, and is accompanied by microscopic signs of inflammation.

In order to understand the condition it is first necessary to study the anatomy and development of the normal cervix. The two Müllerian ducts by their fusion form the Fallopian tubes, uterus, cervix, and vagina. At first these structures are lined by columnar epithelium. Changes occur at a later date whereby the tubes are lined by columnar ciliated epithelium, the uterus by columnar epithelium, and still later the tubular glands appear. In the cervical canal is a mucus-secreting epithelium with many racemose glands. It is not ciliated. It does not pass through the menstrual changes of the uterine endometrium. In the vagina we see the greatest change in the original epithelial lining of the Müllerian ducts, for squamous epithelium, growing from below upwards, replaces the original columnar. Normally this squamous epithelium comes to line the whole vagina; it also covers the cervix and tends to invade the cervical canal. It is found there in a sixth-month foetus, but is later replaced by the columnar epithelium. Occasionally the columnar epithelium of the cervical canal spreads out beyond the external os over the cervix, thus producing the so-called congenital erosion or pseudo-erosion. These congenital anomalies rarely cause trouble in later life, and become covered again by squamous epithelium.

It is known that the vagina may contain organisms in its lower part within forty-eight hours of birth. The lower part of the vagina, therefore, even in a virgin, is not sterile. The upper part of the vagina normally contains the vaginal bacillus of Döderlein. This is non-pathogenic. It is believed to produce an acid substance which, with the secretion from the vagina, forms an acid medium hostile to the growth of pathogenic organisms. Thus pure cultures of streptococci and staphylococci injected into the vagina and cervical canal have been found to be destroyed within a few hours. Winter, Stroganoff, and Menge have shown that bacteria are not normally found above the external os. Curtis confirmed these observations, and has demonstrated that the cervical glands are susceptible to chronic infection.

In chronic cervicitis bacteriological investigation reveals the presence of pathogenic organisms. The organism most commonly found is the staphylococcus, either alone, but usually in combination with the *Bacillus coli*, the streptococcus, and gonococcus. Diphtheroids may also be found, but it is not certain that these should be regarded as pathogenic, for they may be found in the lower part of the vagina during health.

How is the normal protective barrier broken down and access given to these pathogenic organisms?

The invasions of organisms may be the result of a direct infection—for example, gonococcal infection. Indirect infection may follow after injuries to the cervix, such as lacerations of the cervix accompanying childbirth or abortion; or from the upward spread of infection from disease or inflammation of the vulva. The protective acid medium may also be swept away or destroyed by discharge from the uterus, the presence of vaginal pessaries, and by the use of contraceptives and vaginal douching.

Chronic cervicitis is very common. The incidence in a series of 6,483 women examined by Fulkerson was 2,150, or 33.15 per cent. Fulkerson found that the condition occurred in 78 per cent. of cases between the ages of 20 and 40. Burns found it most commonly between the ages of 30 and 40, and next most commonly between 20 and 30. That is to say, it occurs usually during the child-bearing time of life, which supports the view that traumatism of labour or abortion is an important factor in the production of the disease.

The chief symptom is leucorrhoea. This was present in 74 per cent. of Fulkerson's cases. The discharge varies greatly in colour, consistence, and quantity. It is usually of a viscid white mucoid variety, like unboiled white of egg. It may be slightly yellow or green. The discharge is usually more profuse in the morning, on resuming the erect attitude probably, and also just before and after menstruation. In cases in which the infection is of gonococcal origin it may be noticed sometimes that the discharge is more definitely yellow, and is usually muco-purulent. There may be a slight blood-stained discharge on examination or after coitus if a vascular erosion is present. General debility, anaemia, and constipation are not unusually accompanying symptoms. It is not improbable that these are the direct consequence of the absorption of toxic substances from the infected cervical canal. Not infrequently the patient complains of pruritus vulvae due to the vaginal discharge.

Sterility may result from chronic cervicitis. Burns, in a series of 84 cases, found that 37 per cent. were sterile; 39 per cent. had one or more children, no miscarriages; 25 per cent. had one or more children, one or more miscarriages; 2 per cent had miscarriages only. Disorders of menstruation and backache do not occur unless the infec-

* Read in opening a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Manchester, 1929

tion involves also the endometrium or the uterine appendages. Chronic cervicitis of itself does not cause irregular uterine haemorrhage or pain.

It is when we consider the complications which may be consequent upon chronic cervicitis that the importance of the condition is realized. The cervix has been described as the tonsil of the pelvis, and it may act as a focus of infection. The experimental work of Laura Moench has shown that organisms grown from the chronically infected cervical glands of patients suffering from arthritis will produce joint lesions in rabbits, and culturally these organisms are identical with the anaerobic streptococci found in patients suffering from arthritis.

It is known that puerperal pyosalpinx and peritonitis may follow in patients suffering from chronic cervicitis of gonococcal and streptococcal origin. Finally, cervical trauma and cervical erosion may be associated with malignant disease. Bailey has recently reported upon the examination of 850 specimens of the cervix uteri in a paper entitled "An inquiry into the basic cause of cervical cancer; the pathology of cervicitis (cervical erosion) and the relation between cervicitis and cancer of the cervix," in which he was able to trace the changes from erosion to malignant disease.

THE PATHOLOGY OF CHRONIC CERVICITIS.*

BY

GILBERT I. STRACHAN, M.D., M.R.C.P., F.R.C.S.,

ASSISTANT GYNAECOLOGIST, CARDIFF ROYAL INFIRMARY; FIRST ASSISTANT TO THE PROFESSOR OF OBSTETRICS AND GYNAECOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE.

CHRONIC infection of the cervix is by far the most common lesion met with in gynaecological practice. Authorities differ only slightly in their estimates of its frequency, and it is safe to say that, alone or in combination with other lesions, it is present in from 70 to 85 per cent. of all patients seen. British gynaecologists have not given this lesion the attention that it merited, although the recent exhaustive research by K. V. Bailey[1] of Manchester is a most important contribution to the subject. In America and on the Continent, on the other hand, great attention has been paid to the condition in recent years, and a very extensive literature has grown round the subject.

The condition has received many names, such as cervical endometritis, ectropion of the cervix, cervical erosion, cervical catarrh, proliferative adenoma (B. P. Watson[5]), pseudo-adenoma (Eden and Lockyer[2]), cystic disease of the cervix, chronic cervicitis (Moench[4]), and several others. Some of these names are given to different appearances met with at different stages of the disease, while others are based on erroneous ideas of the pathology. The condition is found most commonly in women who have borne children; less commonly it is found in nulliparae; and less commonly still is it present in virgins.

STRUCTURE OF THE CERVIX.

The structure of the cervix is important in this respect. It is covered on its vaginal aspect by stratified squamous epithelium, which contains no glands and which is continuous with the general squamous lining of the vagina. This squamous epithelium is in its deeper basal layer composed of cylindrical cells; superficial to this the main substance of the epithelium is composed of several layers of polygonal "prickle" cells, while the superficial layer or two are composed of flat cells, which are cast off from time to time. From the cylindrical layer are produced by cell division the more superficial layers.

At the external os the squamous epithelium suddenly changes to a high columnar-celled epithelium, with deeply placed nuclei. At numerous sites this epithelium is invaginated deeply into the mucosa, and into the innermost muscular layers of the cervix, to form compound racemose glands. The secretion from these glands and from the epithelium is thick, mucoid, and viscous, and forms the characteristic cervical secretion. Deep to the epithelium on both aspects of the cervix is a scanty stroma which contains few cells, and which merges into the fibro-muscular substance of the cervix.

The high columnar epithelium lining the cervical canal can be followed up to the internal os, when the appearance again suddenly changes as the uterine cavity is reached. Here the epithelium is similar but not so high, the glandular depressions are simple tubules, and the stroma is thick and cellular.

Between these two epithelium-covered surfaces of the cervix is the main muscular and fibrous structure of the viscus. The muscular layers are described as three—an outer and an inner, both longitudinal, and an intermediate one, circular in direction—but in an ordinary section it is difficult to see any regular arrangement of this sort. Fibrous tissue strands lie between the muscular bundles, and thick-walled blood vessels and smaller endothelium-lined lymphatic spaces are also present.

The anatomical relations of the cervix are important from the point of view of its pathology. Above it is continuous with the corpus uteri, and the intermuscular lymphatic spaces of the two communicate. It lies embedded in the pelvic cellular tissue, which stretches out on each side at the bases of the broad ligaments; posteriorly this cellular tissue is incorporated in the utero-sacral ligaments, which are attached to the sacrum on each side of the rectum, while anteriorly the less marked utero-vesical ligaments connect the cervix with the bladder.

THE INFECTIVE PROCESS.

The essential lesion in cervicitis is irritation produced by infection, and this may be brought about in several ways, but the most usual mechanism is chronic pyogenic infection after laceration of the cervix at childbirth. It has to be understood that the extent of the laceration matters not at all; it is the incidence and degree of infection of even a small lacerated surface that counts. The conditions after labour rather predispose to infection. The cervix is patulous, lacerated, and bruised, with the vagina bathed in alkaline lochia instead of the normal acid secretion, and in this way the normal resistance to infection is definitely impaired.

The most commonly found organisms in these cases are the staphylococcus, streptococcus, and *B. coli communis*, but the gonococcus is responsible in a certain proportion of cases. In cervicitis occurring in nulliparae the gonococcus is a more common agent, and here it exercises its well-known ability to penetrate and infect an intact mucous surface. It is very difficult to estimate the exact proportion of all cases which are of gonococcal origin, as the gonococcus soon becomes reinforced and masked by a mixed pyogenic infection, and also tends to disappear into the depths of glandular acini, and so is not obvious in swabs from the cervical canal. It is probable, in our opinion, that the incidence of gonorrhoea as a causative agent in the production of cervicitis is exaggerated.

As a result of infection the changes of inflammation soon appear. While in some cases the inflammation may be acute in the early stages, it is usually only in the late chronic stage, which is discussed here, that the condition is first seen. But it is more than probable that the majority of cases are chronic in type from the onset.

There is oedema of the subepithelial stroma with outpouring of lymphocytes and plasma cells, especially round the blood vessels and the glands, and under the surface epithelium. The blood vessels dilate, the surface columnar and glandular epithelium becomes irritated, so that glandular hypertrophy and distension occur, and the cervical secretion becomes increased in amount and of a muco-purulent appearance from mixture with inflammatory products. This increased inflammatory cervical secretion is known as leucorrhoea. It always retains its thick, viscous tenacity, and it is to be emphasized that, in general, *leucorrhoea is almost always a sign of cervical infection*. Partly as a result of maceration by continual leucorrhoeal discharge, partly by being raised and devitalized by subepithelial oedema, and partly on account of trauma, a plaque of squamous epithelium surrounding the external os becomes separated and cast off in the discharge,

* A paper read in the Section of Obstetrics and Gynaecology at the Manchester Meeting of the British Medical Association in opening a discussion on chronic cervicitis. The paper was illustrated by lantern slides showing the conditions described.

and a raw surface of varying extent is now left wholly or partly surrounding the external os. The columnar epithelium from the cervical canal, being more resistant, is seldom affected in this manner; on the contrary, it is usually stimulated to grow outwards and cover over the raw surface, so that after a time the area round the external os becomes covered by columnar epithelium, which carries with it in its outgrowth cervical racemose glands. This area has a red, raspberry appearance, and the name "cervical erosion" is given to it. It was to this condition of outgrowing endocervical epithelium and glands that Eden and Lockyer gave the name of "pseudo-adenoma."

This erosion is not an ulcer and it is not a granulating patch; it is an epithelium-covered surface, although there is often a breach of continuity between the two types of epithelium at the periphery of the erosion. In the "congenital erosion" this condition of extension of glandular tissue on to the portio is also found, but this is usually regarded as a persistence of a foetal condition, although some observers (Bailey) find inflammatory changes.

If the surface is smooth and the glands few the erosion is called "simple"; if the glands are numerous and dilated, the surface is rough, and the condition is called a "follicular erosion"; while if the glands are numerous but run mostly at right angles to the surface, numerous papillae project upwards between the glands, and it is known as a "papillary erosion." Occasionally these papillae grow to a large size, and constitute the single or multiple mucous polypi often found in this condition. These subdivisions are, however, artificial and unnecessary, and should be discarded.

If the cervix should be definitely lacerated, especially if bilaterally lacerated, it tends to become everted, partly by muscular action and partly as the result of inflammatory infiltration, so that the congested and thick endocervical mucosa is exposed to view. The name "ectropion" is given to this condition of eversion of the endocervical mucosa.

It has to be remembered, then, that the occurrence of erosion marks the first effort at healing on the part of the infected cervix by the covering over of the raw surface by epithelium. After a time the displaced squamous epithelium makes an attempt to reinstate itself. The basal germinal layer grows inwards and insinuates itself beneath the covering columnar epithelium. By cell division more superficial layers of cells are formed, and, with this process continuing, the columnar epithelium may finally be cast off from the eroded surface and confined to its normal bounds.

But prior to this the infection seldom remains limited to the mucosa; usually the fibro-muscular substance of the cervix has also become infected, so that chronic inflammatory hypertrophy is seen, and this, after the process subsides, may be succeeded by fibrosis and atrophy, so that the cervix is finally reduced to a hard nodular condition whose everted lips are shrunken and may be flush with the vaginal vault. Because of the frequency with which the substance of the cervix is infected in this way Moench suggests the appropriate name of "cervicitis" for the condition.

When the squamous epithelium displaces the columnar cells, the racemose glands of the latter are left *in situ*, and their ducts usually become occluded by blockage by epithelium, by blockage by inspissated secretion, or by periglandular fibrosis, and one of two things usually happens. Most commonly the glands continue to secrete; they become increasingly distended with retained secretion, while the lining epithelium, at first columnar, becomes cuboidal, and later flat from pressure. In some cases the epithelium may be unrecognizable as an intact layer. In this way a number of cystic spaces—Nabothian follicles—are formed in the substance of the cervix, and often form projections, especially under the vaginal aspect. In some extreme cases the cervix may be largely occupied by these cysts, but usually they are few in number. It will be evident, then, that the presence of Nabothian follicles indicates an advanced stage of the healing process in this condition, and that when these follicles have developed the red erosion will have disappeared, although fibrosis and puckering of the cervix usually persists.

In other cases the squamous epithelium may grow downwards into the glandular acini, which may become fully occupied by these squamous plugs. Unless this process is recognized these plugs of squamous cells filling the glands may present the appearance of columns of epithelioma, and an unnecessarily grave prognosis be given.

The final structural result, then, to the cervix consists of fibrosis and eversion, with some persistent Nabothian follicles.

Late Results of Cervicitis.

The sequelae of the condition may now be considered. They are many and important, and may be grave. The parametrium is frequently affected by lymphatic extension from the cervix, so that in the early stages tender infiltration and in later stages fibrosis is produced. The bases of the broad ligaments are often affected in this way, and frequently a tight fibrous scar can be felt stretching over one or other fornix from the edge of an eroded laceration. Equally often the utero-sacral ligaments are involved, and, on pulling the cervix forwards, pain in the lower part of the back is elicited.

These parametrial extensions are the most common causes of backache or chronic pelvic pain in women.

Absorption of toxins from the chronically inflamed cervical surface leads in some cases to a degree of general ill health, and it is probable, as shown by clinical experience, that some cases of muscular rheumatism and osteo-arthritis are due to such toxic absorption. Young[4] has recently cited examples of these complications, and I have also had experience of several cases which benefited largely by repair or amputation of the cervix. The presence of a continual vaginal discharge, again, may cause definite mental distress, but its effect in bringing about mental disease has probably been exaggerated. Sterility, and a tendency to puerperal sepsis, have been described as complications of this condition, but clinical experience does not bear this out. The majority of these patients have had a number of children, and when their labours have been normal no special tendency to pyrexia has been noted.

Direct extension to the uterine mucosa is not common, but as the lymphatics of the cervix and body are associated, chronic infection of the musculature of the uterus may occur, and the condition of chronic metritis develop. The main symptom here is menorrhagia with uterine enlargement, and this always indicates uterine involvement. Menorrhagia is not a symptom of uncomplicated cervical infection. In the same way, by lymphatic extension, the tubes and ovaries are commonly affected, and chronic salpingo-oöphoritis may be produced, with resulting pelvic pain and sterility.

On account of prolonged leucorrhoeal discharge pruritus vulvae may develop, while in gonorrhoeal cases prolonged vulval irritation may produce a crop of irritating condylomata.

But the most important sequel is carcinoma. It is often a late sequel, occurring many years after the injury was inflicted. Carcinoma of the cervix usually occurs in patients who have had a child or children, and it is just these women who have had cervical damage and erosion. In this connexion Farrar[3] recently reported that of 300 cases of carcinoma 96 per cent. had had one or more children. Similar figures are quoted by other writers, and my own experience is in general agreement with this.

So far as is known there is no marked tendency for the patient with the congenital erosion or the nullipara with the gonorrhoeal erosion to develop carcinoma, so we are forced to the conclusion that it is not merely the erosion, but the damage to the cervix at childbirth associated with the erosion, which is the predisposing factor in this connexion. This is borne out by the fact that most patients with carcinoma of the cervix have not had one but several pregnancies.

When we consider the long-continued irritation, the great epithelial proliferation which is stimulated, and the damage, often repeated, of childbirth, the wonder is that carcinoma is not a more common sequel than is the case.

Carcinomatous overgrowth usually occurs in the squamous epithelium, and the first thing noticed is that the basal germinal layer proliferates in columns and breaks through its basement membrane. The cell columns penetrate

deeply into the substance of the cervix, and even before surface ulceration occurs a well-marked lymphocytic barrier is thrown out in an attempt, usually vain, to control the proliferating cells. Similar changes may occur in connexion with the glandular epithelium. When extensions occur, it is very common to find them most marked in the utero-sacral ligaments or along the thickened base of one or other broad ligament, the very places that have been previously affected by chronic irritative fibrosis.

Conclusion.

A study of this pathology shows us that the cervix is one of the most important pelvic structures and that chronic inflammation here is a widespread condition which may have far-reaching immediate and late results.

Another important point emerges that, while severe puerperal sepsis accompanied by pyrexia occurs in about four cases per thousand, puerperal sepsis in a minor degree, often with no symptoms at the time, lasting many years, and with a risk of carcinoma formation, occurs in a large proportion of all parturient women.

The main etiological factor in this condition is injury at childbirth, and these cervical injuries represent the wounds which women in labour receive in the process of producing the next generation.

The medical and sociological considerations raised by a study of this subject are very large and important, and there is no aspect of obstetrics and gynaecology which is more worthy of our attention.

Leucorrhoea may be produced by other lesions, such as tuberculous or syphilitic cervical ulcers, or foreign bodies, but only the more common lesion can be discussed in this paper.

TREATMENT OF CHRONIC ENDOCERVICITIS.*

BY

R. S. STATHAM, O.B.E., M.D., CH.M.,

HONORARY GYNAECOLOGIST, BRISTOL ROYAL INFIRMARY; LECTURER IN OBSTETRICS, UNIVERSITY OF BRISTOL; MEDICAL OFFICER IN VENEREAL DISEASE CLINIC, BRISTOL.

WHEN I was asked if I would open a discussion on the treatment of chronic endocervicitis at this meeting, I felt much flattered at the honour done to me, but I accepted with grave misgivings when I came to consider the subject which had been assigned to me. I do not think there is any gynaecological condition which is seen so frequently by doctors in all types of practice, and which is more difficult to treat satisfactorily. It is presumably on account of this difficulty that the methods of treatment advised are so numerous and diverse; owing to this I am unable to put forward any authoritative bibliography, and this paper expresses merely my own personal preferences.

That the condition requires treatment, and effectual treatment at that, is obvious when its complications are considered. Quite apart from the personal discomfort and annoyance which chronic leucorrhoea causes to patients of cleanly habits, it bears in its train a series of sequelae of great importance. It is one of the commonest causes of sterility and—perhaps even more often—of the one-child marriage. Again, owing to the deep ramifications of the glands of the endocervix, and their close relationship to the lymphatics draining into the base of the broad ligaments, it is a very common cause of a mild thickening and inflammation of the pelvic cellular tissues in that region. This condition is very much commoner than is generally realized, and gives rise to pressure on, and nipping of, the ureter, with symptoms of chronic backache and renal pain. This has been most clearly worked out and described in numerous papers by Guy Hunner,[1] and for some years I have been in the habit of passing acorn-headed ureteric bougies up the ureters in cases of backache associated with "erosion," and it is astonishing how often there is found a well-defined stricture of the ureter about the situation where it passes across the cervix below the uterine artery. The worst complication which can ensue is carcinoma of the cervix, and I am sure it is generally agreed that there is now no question as to the close relationship between the incidence of chronic infected lacerations and cancer of the cervix; so that if there were no other reasons at all, this fact alone would justify any attempt at curing these infections. It is not my province to discuss the pathology of this condition, but when it is reviewed it will be seen that there are two factors to be treated: (1) the leucorrhoea and so called *erosion*; (2) the deep infection of the cervical tissues with its surrounding infiltration. The former is much easier to attack and conquer than is the latter when once it is well established, and I would press for the early treatment of all lacerations of the cervix, and also for all established "erosions." This particularly applies to lacerations diagnosed at the time of the confinement, which can easily be sutured immediately, or before the puerperium is concluded. De Lee[2] states in his textbook that he has never seen a carcinoma follow on a laceration which has been properly repaired at the time when it occurred.

Although leucorrhoea may be one of the symptoms of a variety of gynaecological conditions this paper is concerned only with chronic infection of the endocervix, and no attempt is made to discuss the diagnosis or treatment of any of the other conditions giving rise to similar symptoms.

Coming now to the actual treatment of the condition of chronic endocervicitis, when it is established, we are at once faced with the problem of the individuality of the patient. It is impossible to apply the same rules of treatment to the patient with an extensive laceration as to the one with no tear at all. It is equally useless to group together the young woman with an infection following her first childbirth and the patient of 55 who will not become pregnant again. Each case must be considered on its merits, and to some extent the cause of the lesion will direct the method of its cure.

For some years I have had the great advantage of being on the staff of the Bristol venereal clinic as well as being gynaecologist to the Royal Infirmary, and I am firmly convinced that gonorrhoea is far more commonly at the bottom of a chronic cervical infection than is usually thought. In my gynaecological out-patient clinic smears are taken from the urethra and cervix of all cases of leucorrhoea, and quite a large proportion are returned showing gonococci present, when the case is transferred to the venereal disease clinic for treatment. The converse also holds good. I have now seen a very large number of cases of gonorrhoea which have developed erosions of the cervix while under treatment, and this condition persists when no trace of the gonococcus can be obtained with the most careful methods of taking smears and cultures. I would like to stress the importance of paying no attention to the presence or absence of a discharge in deciding as to whether a gonorrhoea is cured. because the leucorrhoea associated with the resulting chronic endocervicitis will persist for a very long time after the actual gonococcal infection is cured. It is therefore, in my opinion, necessary to examine all cases of chronic cervical infection for gonococci—by smears from urethra, cervix, and Bartholin's glands—before commencing further treatment.

If the presence of the gonococcus can be demonstrated I consider that there is no treatment so good as that of daily douching with boric acid, wiping away the mucopus, and then thoroughly swabbing the cervix and vaginal vault with 1 per cent. mercurochrome.* I think the stronger solutions defeat their object by delaying the normal process of healing—that is, the replacement of the columnar-celled erosion by the normal squamous-celled covering of the vaginal surface of the cervix. In all

* Read in opening a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association, Manchester, 1929.

cases of recent infection with much muco-purulent discharge—even though they are not gonorrhoeal—I find mercurochrome most excellent, while 1 in 1,000 flavine solution makes a most useful change.*

The above is the method of treatment I use in all fairly recent infections of the cervix which are not complicated by erosion or extensive laceration. In cases where the cervical canal is obviously infected fairly high up, a Playfair's probe can be used to carry the solution as high as the internal os. Probably the next most useful remedy is 10 per cent. silver nitrate used in a similar manner. I have had little or no success with the old-fashioned iodized phenol, as the infection usually recurs within a few weeks. A recent form of treatment, of which I have no personal experience, though it is used by my colleague Dr. H. L. Shepherd, is the local application of vaccines to the endocervix; but, while he is enthusiastic, he has not yet treated a sufficient number of cases to form a final opinion as to its value.

It will be seen that the best forms of treatment for purulent endocervicitis must be administered by an attendant; it is quite useless to supply patients with a douche can and materials to use in it and let them treat themselves, and it is quite obvious that they cannot possibly swab the cervix and upper vagina with the antiseptic selected. These difficulties arise in the treatment of private patients. At the Bristol Royal Infirmary the matron has very kindly arranged for a "douching clinic" to be held every morning, and patients attend for daily treatment, which is carried out by a skilled nurse. The results have exceeded our best expectations. The patients are enthusiastic over the rapid amelioration of their discomfort, while a great advantage is gained by the hospital in the falling off in the numbers of the cases of this type requiring admission to the wards.

When the cervical infection is accompanied by laceration it will be found that many patients present themselves complaining of dull pain in the groins and backache. In these cases the base of the broad ligament will be found to be thickened and tender on one or both sides, the ureters are often palpable and tender, and the patient complains of frequency of micturition and usually shows a quite considerable bacilluria. This mild-grade cellulitis, with its consequent fibrosis and contraction, may cause far more discomfort to the patient than the actual laceration and infection. I have found that really hot and prolonged douching is by far the most efficient remedy. The douche is given as hot as it can be borne, and is continued for at least fifteen minutes. This requires very large quantities of fluid (about twenty pints), and is not easy to manage in the ordinary way. In the out-patient department we have made special arrangements at the "douching clinic," but in private cases the procedure can be made comparatively simple when carried out as follows: The patient lies in a warm bath, and a large douche can is hung upon a conveniently placed nail. The douche nozzle is inserted to the top of the vagina, and the can is then replenished from the hot tap as often as is desired, while the presence of the warm water in the bath prevents too rapid an outflow. If there is much pus the patient is told to give herself a short lysol douche in the usual way before getting into the bath. The relief thus obtained is immediate, and usually becomes permanent after a short time. Should the symptoms still persist I explore the ureters for stricture by Hunner's method.[5]

Glycerin, or glycerin and ichthyol, tampons are of use only when applied by an expert nurse or by the medical attendant, otherwise they are positively harmful. The patient never manages to get them right up to the vaginal vault, and so a gap is left between the cervix and the tampon. Owing to the hygroscopic action of the glycerin a pool of muco-purulent fluid forms and bathes the cervix, which becomes sodden and sheds still more of its squamous epithelium, and the condition of the cervix becomes worse rather than better, while very little improvement, if any, is produced in the thickening of the broad ligament.

Another most excellent remedial method is the use of hot antiphlogistine tampons. These are formed of a cup-shaped lump of antiphlogistine enclosed in a single layer of gauze, heated as hot as can be borne and pressed well moulded right up against the vaginal vault, to be removed after six hours. It requires expert insertion, but an intelligent nurse can learn how to apply it when she has tried it two or three times under supervision.

The practice, once so frequent, of putting in ring pessaries to relieve the backache cannot be too strongly condemned; it tends to keep up the cervical infection and presses upon the tender fornices and ureters. It is far better to remove any pessary during treatment, even though there should be a considerable degree of prolapse.

Very excellent results are also obtained with diathermy using a current which the patient can just endure with comfort, and it is especially useful in the treatment of gonorrhoeal cases when used with the technique advised by Cumberbatch.[4]

So far the treatment discussed has been that of cases of fairly recent origin; it now remains to consider the more chronic type of endocervicitis, which resists the above methods of treatment. I do not think there is any question that the treatment of these resistant cases must be operative, and I include the use of the cautery under this heading. For some time past I have been using the electro-cautery in the treatment of chronic cervicitis with the greatest success. It has been enthusiastically advocated by Hunner and by Kelly,[6] while Matthews[5] has compared the value of treatment by the cautery with surgical treatment, to the advantage of the former.

In cases with ectropion of the cervix accompanied by erosion the electro-cautery is used to draw a series of radiating lines from the os to the edge of the affected area, the patient being warned that the discharge will be worse for a few days. The results are most striking; the swollen and everted mucosa shrinks rapidly, and the whole cervix improves astonishingly quickly. The treatment is repeated weekly until cure is effected. It has the great merit of being practically painless, and requires no anaesthetic at all; none of my patients has complained of more than a slight pricking, and they return without the least anxiety for their weekly treatment. The same procedure is utilized in those cases where the cervical canal is infected without much erosion being present. Here a cautery point is inserted up the canal and drawn up and down once or twice. If there is very much eversion and rolling out of the mucosa a short anaesthetic—for example, nitrous oxide—can be given and a much heavier cautery point may be used to cauterize the tissues more deeply. In these cases the treatment should be repeated at intervals of a month, and not of a week. I personally prefer light cautery and more frequent treatment, as there is then no danger of contraction of scar tissue. In either case I order a daily saline douche for a few days after the treatment to deal with the temporary increase in the discharge.

When the endocervicitis is complicated by laceration it becomes urgently necessary to treat the condition by operation, owing to the relatively great predisposition to carcinoma. The operations possible fall into three groups: (*a*) repair operations; (*b*) amputations of the cervix; and (*c*) panhysterectomy. Whichever operation is eventually decided upon, the condition of the perineum and pelvic floor should always be taken into consideration, and a perineorrhaphy should be performed when required. The main deciding factor as to the type of operation chosen is the question of the probability of further pregnancies. In young patients I do not think that amputation of the cervix is usually advisable. In some cases it is followed by abortion, and in one of my own cases there was severe cicatrization, which caused much trouble in a subsequent labour. If amputation is performed for hypertrophy of the cervix it should be of the "low" variety in young women. I prefer to repair the cervix by a plastic operation, denuding the lateral scarred areas and suturing them together, the classic operation of Emmett requiring too long a preparation and not always curing the erosions. This gives a very good result, and I have inspected a large number of these cases two years after operation and found it difficult to believe that they had ever shown the large tears and erosions described in their notes. In patients who are unlikely to become pregnant again an amputation of the cervix is the best procedure. I prefer the operation

* If mercurochrome is used, it must be a reliable brand. Many failures are due to the fact that there are substances on the market which are not mercurochrome at all, although they resemble it in appearance.

of Victor Bonney (sometimes associated with the name of Stumndorf), the only precaution necessary being firm ligation of the lateral vessels, as this operation can cause really dangerous post-operative bleeding. An excellent modification is described by Te Linde[10] for amputation at a lower level, and is very useful in patients who might possibly become pregnant again. In most of my cases the perineum also has required repair, which is done at the same time.

In elderly patients, especially if there is reason to suspect any uterine complications, such as the so-called "fibrosis uteri," the operation of election is a panhysterectomy. It is most disappointing to perform an amputation of the cervix and have the patient returned in six or eight months with intractable uterine haemorrhage. In many patients of this class the perineum is torn and the pelvic floor has yielded, so that there is a very considerable degree of prolapse. For these there is no operation so good as that of vaginal hysterectomy, with repair of the pelvic floor and perineum. At the Bristol Royal Infirmary we use the technique of G. V. Ward,[11] which is a modification of the Mayo operation. We have had no trouble with shock or bleeding, and the results have been surprisingly good, the perineum and vagina becoming anatomically reconstructed. I think that the operation of vaginal hysterectomy has been much neglected of recent years, and my own experience is in complete accord with that of Professor Green-Armytage described in his recent paper.[3] I would, however, urge the complete repair of the pelvic outlet at the same time. The combined operation causes little or no shock, and is easily performed, while in fat patients it is enormously superior in every way to an abdominal hysterectomy with a separate repair operation.

If true ulceration is found upon the cervix it is essential to remove a portion of its growing edge for sectioning. Whilst carcinoma is much the most likely complication, the possibility of tubercle or gumma must not be overlooked, and in all gonorrhoeal cases it should be part of the routine treatment to take a Wassermann test. It is very surprising how many patients with chronic gonorrhoea are also syphilitic. In these cases I defer operation till the patient has had twelve months' routine antisyphilitic treatment.

Finally, as prevention is better than cure, I would again urge the importance of inspecting the cervix after delivery and suturing all considerable tears. It is surprisingly easy to press down the fundus till the cervix appears at the outlet, and then it can be quite easily inspected with the labia separated by two fingers. I feel sure that if this procedure were taught and practised more there would be a great decrease in the incidence of chronic endocervicitis, and therefore of carcinoma of the cervix.

THE TREATMENT OF INFLUENZA WITH S.U.P. 36.

BY

RAYMOND M. PEARCE, M.B., Ch.B.,

HALIFAX.

The drug S.U.P. 36 is a symmetrical urea, and its full chemical name is para-benzoyl-para-amino-benzoyl-amino-naphthol 3 : 6 sodium sulphonate.

During the influenza epidemic in the spring of the present year I endeavoured to make a systematic test of the advantages of treating influenza by intramuscular injections of this drug. Every case of influenza seen, in which the disease had not existed for more than forty-eight hours, was used for my records, alternate cases being treated by injection of S.U.P. 36 and the remaining cases orally by drugs such as salicylates, aspirin, and influenza mixtures. Cases not first seen until more than forty-eight hours after the onset of the disease were not taken into account, as it was not expected that the injection of S.U.P. 36 could be of much use after the acute phase had passed.

The method employed in the injected cases was to inject as early as possible an initial dose of 0.5 c.cm. (representing 0.005 gram). This was followed by an injection of 0.75 c.cm. on the fourth day following the initial dose if the case had not cleared up in the meantime. In some cases the initial dose given was 0.75 c.cm. The injections were usually made into the gluteus medius muscle, and only very trivial complaints of pain were ever received. Occasionally the injections were made into the deltoid muscles, where in one or two cases rather more pain was suffered. The only drugs given orally to any of the patients treated with S.U.P. 36 were calomel, 2 to 5 grains, where indicated—that is, in roughly half the injected patients—and the use of a simple expectorant mixture where necessary (in only about 10 per cent. of the injected patients). In no other injected patients, excepting the two noted with cardiac trouble, were any other drugs given.

At the end of a fortnight it became quite evident to me that the injected patients had the advantage over the non-injected ones, and thereafter I treated by injection all patients who would submit to the treatment.

The epidemic of influenza prevailing was of the somewhat mild type. The onset was very acute, with a sudden rise of temperature to 101° to 103°, with pain in the limbs and back, fairly severe headache, and in many cases a particularly troublesome cough with little expectoration. Pulmonary complications were rare and the mortality was low, no death being recorded among the series of cases investigated.

It was found to be difficult in practice to collect data which would be of value for tabulation in a comparative manner between injected and non-injected cases, but, taking five headings as the main symptoms in the disease, comparison may be drawn in the following manner:

	Control Cases.	Injected Cases.
Average duration of pyrexia in days	2.8	1.4
Average duration of headache in days	2.1	1.0
Average duration of muscular pain in days ...	3.4	1.3
Average number of days in bed	5.7	2.8
Average number of days off work	16.0	6.9

At first sight it may appear that these comparisons are subject to many fallacies and therefore not of much value, but, taking into consideration the following points, I think, though the numbers are small, that the five comparisons drawn give a fairly accurate idea of the progress of the attack.

The average age in each group was: Controls 33.9 years; injected cases 34.8 years.

The sexes of the two groups were: Controls 40 per cent. males; injected 57 per cent. males.

The class of patient treated in each group was similar.

No attempt was made to hurry the injected patients out of bed or back to work, and in many cases they were purposely kept in bed some time after their temperature was normal.

From a comparison of these figures it will be seen that in the injected group the duration of pyrexia and headache is halved, while the duration of muscular pain is even more than halved. The time in bed is also halved, but this is perhaps the least reliable of the figures for comparison. The figure for the average time off work may, I think, be taken as reliable, and is again seen to be slightly more than halved in the injected cases.

A careful study of the injected cases reveals the fact that the earlier the injection is given the greater is the benefit derived, and this was even more obvious from the clinical study of the cases themselves. As a matter of interest, several patients seen too late to be included in the comparative records were given their initial dose on the third, fourth, and in one instance on the fifth day of the disease, and in none of these cases was any benefit noticed

from the injection. This fact is noteworthy, as it may be of importance in determining how the beneficial effect of the injection of such drugs as S.U.P. 36 is brought about, and is a point which warrants further investigation. One very interesting clinical phenomenon observed after injection was the almost entire absence of perspiration during the period of the abatement of pyrexia. So noticeable was this that in many cases my attention was drawn to the dryness of the patient's skin by other members of the family, and in several cases of pneumonia which I have treated with S.U.P. 36 the same absence of perspiration has been noticed by nurses in attendance.

The following clinical notes were taken on the individual cases.

Case 1a.—Mr. W., aged 26. Typical influenza. Temperature 102°. 0.5 c.cm. S.U.P. 36 injected into the gluteus medius muscle. Next day the temperature was normal, but patient still felt poorly. On the third day patient got up, feeling better, and made an uninterrupted recovery, returning to work on the seventh day. In this case no second injection was necessary.

Case 2a.—Mr. J. A. S., aged 19. Typical influenza. Temperature 101°. On February 22nd 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. Twenty-four hours later the temperature was normal, but some bronchial catarrh was present and patient was kept in bed for three days. He returned to work completely recovered in fourteen days.

Case 3a.—Mr. L., aged 40. Typical influenza. Temperature 101.6°. Headache very severe, muscular pains slight. 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. Twenty-four hours later the temperature was normal, the headache and muscular pains having passed away within twelve hours from the injection. Patient was in bed for two days. Complete recovery and return to work on the sixth day.

Case 4a.—Mr. J., aged 35. Typical influenza. This patient says that he "always has 'flu' whenever it is about," and I have previously treated him for two rather severe attacks of influenza during the past three years. Patient on this occasion was first seen with a temperature of 103°, sweating profusely, headache and muscular pains very severe. As he had been dosed with quinine by his wife no injection was made on this day. The next day 0.75 c.cm. S.U.P. 36 was injected into the gluteus medius, the temperature at this time being still 102° and the pains and general condition the same as on the previous day. During the next twenty-four hours improvement was most marked and the temperature became normal, the patient getting up of his own accord twenty-four hours after the injection. He resumed his work, completely recovered, on the sixth day. Three points are of interest: (1) The condition was completely stationary for twenty-four hours before the injection. (2) The profuse sweating ceased almost immediately after the injection was made. (3) The patient is particularly subject to influenza, and is convinced that he has never before recovered in anything like so short a time.

Case 5a.—Mr. R., aged 24. Typical influenza. Temperature 102.6°; muscular pains very severe, and severe headache. 0.5 c.cm. S.U.P. 36 injected into gluteus medius. Twenty-four hours later the temperature was normal, the headache had been relieved within twelve hours, and the muscular pains within twenty-four hours. Patient was kept in bed for three days, and recovery was complete in seven days.

Case 6a.—Mrs. S., aged 29. Typical influenza. Temperature 101°. 0.5 c.cm. S.U.P. 36 injected into gluteus medius. Twenty-four hours later temperature still 101°. The next day the temperature was normal, but patient still felt ill and was given a second injection of 0.75 c.cm. of S.U.P. 36. The following day the patient got up, and she returned to work recovered on the ninth day.

Case 7a.—Mrs. F., aged 27. Typical influenza. Temperature 102°, with exceptionally severe muscular pain and severe headache. 0.5 c.cm. S.U.P. 36 injected into deltoid muscle. Twenty-four hours later the temperature was normal; the muscle pain and headache had both disappeared within twelve hours of injection. Patient was in bed only two days and returned to work on the fourth day. She had complained of pain in the injected arm lasting twenty-four hours.

Case 8a.—Mrs. M., aged 32. Typical influenza. Temperature 102°. On February 25th 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius; twenty-four hours later the temperature was 100.6°. On February 27th the temperature was normal and the patient feeling quite well, but the next day slight tonsillitis developed, and on March 1st an injection of 0.75 c.cm. was given. The patient was again seen on the following day, when all the symptoms had cleared up, the attack of tonsillitis being apparently aborted. Return to work was made ten days from onset.

Case 9a.—Mrs. P., aged 38. Typical onset of influenza. Seen in the very early stages with a temperature of 101.6°, headache, and severe muscular pain, all of only a few hours' standing. At 11 a.m. 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. Almost complete relief of both headache and muscular pain was obtained by 11 p.m. the same day, at which time the temperature was still only 101°. Four days later a second injection of 0.75 c.cm. was given; the next day the patient was quite well and doing her work. An interesting point in this case is that prior to the attack of influenza the patient had suffered from chronic nasal catarrh for some weeks. This completely cleared up following the injections, and there has been no recurrence up to the present date—July 9th.

Case 10a.—Mr. S. C., aged 46. Typical influenza. 0.5 c.cm. S.U.P. 36 injected into gluteus muscle. Two days later the temperature still remained high, and on the fourth day a second injection of 0.75 c.cm. was given. The patient was in bed five days and off work twelve days.

Case 11a.—Mr. B. C., aged 57. Typical influenza. Temperature 102.6°. On February 26th 0.5 c.cm. S.U.P. 36 was injected into gluteus medius. This patient was not seen the following day, on February 28th the temperature was normal. The patient kept in bed for four days, a second injection of 0.75 being given on the fourth day. He resumed work, recovered, on the fourteenth day.

Case 12a.—Mrs. L. S., aged 35. Typical influenza. Temperature 102°; muscular pains and headache both severe. 0.5 c.cm. S.U.P. injected into gluteus medius. Twenty-four hours later the temperature was normal and pain and headache had both disappeared. Patient was in bed three days, and had completely recovered six days.

Case 13a.—Baby R., aged 3 (boy). Typical influenza (infection from other members of the household). The child was seen at 7.30 p.m., and was decidedly ill with a temperature of 104.6° and violent delirium. (There was no constipation or gastric disturbance to account for this.) 0.75 c.cm. S.U.P. 36 was injected into the gluteus at 7.30 p.m. The child had settled down by midnight and had a good night. At 10 o'clock next morning the temperature was 100°. No other treatment whatever was given in this case, and no further injection was given. The child was kept in its cot for four days, and was completely recovered by the fifth day.

Case 14a.—Mrs. J., aged 36. Typical influenza. Temperature 102°; muscular pains very severe. 0.5 c.cm. S.U.P. 36 injected into gluteus muscle. Twelve hours later the temperature was normal and all muscular pain had disappeared. The patient was kept in bed for two days, and returned to work recovered in six days.

Case 15a.—Mrs. O., aged 24. Severe case of typical influenza. Temperature 103°. 0.5 c.cm. S.U.P. 36 injected into gluteus medius. Twenty-four hours later the temperature was normal and all other symptoms had disappeared, but the patient complained of feeling very weak and was kept in bed for five days, 0.75 c.cm. being injected on the fourth day. Complete recovery and return to work on the tenth day.

Case 16a.—Mrs. H., aged 35. Very early case of typical influenza. Infection from other members of the household, and on the first signs patient went to bed. Temperature was then 100° and pain was complained of, especially at the back of the neck. 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. Next day the temperature was normal and all pain gone. The patient was up and resumed her work the following day. No further injection was given.

Case 17a.—Mr. H., aged 40. Influenza with tonsillitis. Temperature 102.6°. On February 27th 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. On March 1st the patient was very much better, and two days later the temperature was normal and patient got up. On March 5th he had quite recovered. In this case pain was complained of after the injection and a second injection was refused. Experience had now shown me that this type of case does better if the initial dose injected is 0.75 c.cm.

Case 18a.—Miss I. B., aged 27. Typical influenza. This patient is a weakly and a neurotic type of girl. On February 27th the temperature was 102°, when 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. Twenty-four hours later the temperature was 100.6°, with marked improvement generally. On March 3rd patient got up feeling quite well. Rather long convalescence until March 23rd, when she returned to her work.

Case 19a.—Mrs. W., aged 30. Early case of typical influenza. Patient sent to bed with temperature of 101°, and 0.5 c.cm. S.U.P. 36 injected into gluteus medius. All the symptoms quickly subsided; the patient was up forty-eight hours after the injection, and resumed her housework on the third day.

Case 20a.—Mrs. M., aged 25. Severe case of typical influenza. Temperature 103°, with very severe headache, troublesome cough, and the patient felt very ill. On March 1st, when first seen, 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. On the following day the temperature was 101° and the patient felt much better. The next day the temperature had fallen to normal. On March 5th the temperature was still normal, but patient complained of muscular pain, so a second injection of 0.75 c.cm. was given. Two days later the patient got up. On March 10th she was quite well.

Case 21a.—Mr. P., aged 34. Early case of typical influenza. Temperature 101.6° on March 3rd, when 0.75 c.cm. S.U.P. 36 was injected into the gluteus medius. In twenty-four hours the temperature was normal and all pain had disappeared. On March 6th the patient had quite recovered. He returned to work on the seventh day.

Case 22a.—Miss P., aged 29. Early case of typical influenza. On March 5th, when the temperature was 101°, 0.5 c.cm. S.U.P. 36 was injected into the deltoid muscle. On March 7th the temperature was normal and the patient got up. On March 9th a second injection of 0.75 c.cm. was given into the deltoid of the other arm. Patient resumed her work nine days from the onset. No complaint of pain in either arm was made.

Case 23a.—Mr. P., aged about 40. Typical influenza with tonsillitis. On March 5th 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. Two days later there was marked improvement and the tonsillitis was clearing up. On March 9th a second injection of 0.75 c.cm. was given. The patient was fit for work on March 15th.

Case 27a.—Mr. W., aged about 26. Typical severe case of influenza. Temperature 104°, severe muscle pains, headache, and bronchial catarrh. On March 6th 0.75 c.cm. S.U.P. 36 was injected into the gluteus medius. Twenty-four hours later the temperature had fallen to normal, the headache had disappeared, but the muscular pains persisted. On March 8th the muscular pains had gone, and the patient got up of his own accord. The next day the patient felt so well that he went to his work for a short time, but in the evening another injection of 0.75 c.cm. was given. On the morning of the following day the patient again went to his work, and continued without interruption.

Case 28a.—Mr. H., aged 31. Typical influenza. Temperature 103°; muscular pains and headache both severe. 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. Twenty-four hours after injection the temperature was normal, the headache relieved, and muscular pain less severe. The patient was kept in bed for four days, and a second injection of 0.75 c.cm. was given on the fourth day. Complete recovery followed, and he was able to return to work on the seventh day.

Case 26a.—Mr. M. H., aged about 45. Seen in the early stages of onset of influenza. 0.75 c.cm. S.U.P. 36 was injected into the muscle of the forearm at 11 a.m. The patient went to bed at noon the same day, and was up and at work feeling fit the next morning. No further injection was given, the attack having apparently been completely aborted.

Case 25a.—Mr. F., aged 35. Typical influenza of a severe type. *Temperature 104°, with very severe pain in head and muscles.* Cough and signs of bronchitis were present. 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius on March 5th—that is, the second day after onset of the symptoms. The next day little improvement was noticed, but the temperature was down to 101.4°. On March 7th pneumonia of the influenzal type developed and the patient was decidedly ill. The next day 0.75 c.cm. was injected. On March 9th the patient was much improved in every way, and the improvement continued without a further injection being necessary, the temperature falling by lysis and becoming normal on the seventh day from the onset of the pneumonia. Convalescence was uneventful.

Case 24a.—Mr. J., aged 40. Influenza and tonsillitis. On March 6th the temperature was 102°, and 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. The next day the temperature had fallen to normal and there was marked improvement generally. On March 10th a second injection of 0.75 c.cm. was given, the patient getting up the following day. On March 14th the patient was quite well and attended the surgery, asking to return to work.

Case 29a.—Miss M. R., aged 19. Typical influenza. On March 6th 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. The next day there was marked improvement with normal temperature. On March 9th the patient was not so well and the temperature had risen to 100.2°, so a second injection of 0.75 c.cm. was made into the gluteus medius. On March 11th the patient was up and feeling quite well. She returned to her work on the eighth day from onset, remarking that she had had influenza three times previously and had always been obliged to stay away from work for two to three weeks.

Case 30a.—Mrs. M. R., aged 49. Typical influenza. The second case in the same household as Case 29a. Immediately the first symptoms showed themselves, and when the temperature was 99.4° at 10 a.m. and pains in the back were complained of, 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. All symptoms subsided in twelve hours, the attack apparently being completely aborted. No second injection was given.

Case 31a.—Mr. R., aged 50. Early case of typical influenza. Third case in the same household as Cases 29a and 30a. 0.5 c.cm. S.U.P. 36 was injected into the deltoid muscle on the first onset of symptoms. The attack appeared to be completely aborted, the patient only missing one day's work.

Case 32a.—Miss E. S., aged 53. This patient suffered from *chronic bronchitis and chronic mitral endocarditis.* Auricular fibrillation was present at the time of the onset of an attack of typical influenza, and the patient was obviously dangerously ill. 0.75 c.cm. S.U.P. 36 was injected into the gluteus medius, and this dose was repeated two days later. Massive doses of digitalis were given by the mouth for the treatment of the fibrillation, on the lines of Cole's treatment. The influenzal symptoms subsided rapidly, marked improvement being made in the first sixteen hours, and recovery was uneventful, the heart responding well to digitalis.

Case 33a.—Mr. M., aged 33. Typical influenza. Temperature 102°, muscle pains and headache both severe. 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. Twelve hours later the headache and pain had disappeared, the temperature being normal twenty-four hours after injection. The patient was in bed three days, and had completely recovered in five days.

Case 34a.—Mr. B., aged 56. Influenza of the gastric type, with vomiting and diarrhoea. 0.75 c.cm. S.U.P. 36 was injected into the gluteus medius as the initial dose. Twenty-four hours later the temperature was normal, and vomiting and diarrhoea had ceased. The patient returned to his work eight days from the onset, having been in bed three days. This case is of interest as being the only case of the gastric type in the series, and no other medicine whatever was given, this not being one of the cases to receive calomel.

Case 35a.—Mr. J. H., aged 48. Influenza and tonsillitis. 0.5 c.cm. S.U.P. 36 injected into the gluteus medius. Temperature became normal by the third day, and on the fourth day a second injection of 0.75 c.cm. was given. Patient got up on the fifth day and was off work for ten days from the onset. This is another instance of a patient who should have received 0.75 c.cm. as the initial dose.

Case 36a.—Miss E. M., aged 35. This patient has a bad chronic mitral lesion and was treated for auricular fibrillation two years ago, remaining on a small dose of digitalis ever since. She was seen on March 7th with typical symptoms of influenza, temperature 101°, and severe pains in back and limbs. 0.75 c.cm. S.U.P. 36 was injected into the gluteus medius as the initial dose, and all symptoms subsided and the temperature became normal within forty-eight hours. The patient was kept in bed for five days, and returned to work completely recovered in eight days from the onset.

Case 37a.—Mr. T., aged 43. Typical influenza; second attack this year. On March 9th the temperature was 102.6°. 0.75 c.cm. S.U.P. 36 was injected into the gluteus medius as the initial dose. The next day the temperature was still 102°. On March 11th the temperature was normal and all other symptoms had subsided. The patient was then feeling quite well and asking to get up. He returned to work on March 13th.

Case 38a.—Mrs. B., aged 49. Typical influenza, but pain in the back especially marked. On March 11th 0.5 c.cm. S.U.P. 36 was injected into the gluteus medius. On the following day very great improvement was noted. On March 14th 0.75 c.cm. was injected into the gluteus. Two days later the patient was quite well and returned to work. The severity of the pain in the back was of interest in this case, as the patient was told to report if there was any return of this pain. She did not do so, but I have since seen her, and she remarked voluntarily that, whereas in previous attacks of influenza she had always been troubled by pain in the back continuing after the attack, she had this time been quite free from pain.

Case 39a.—Miss N. D., aged 24, came to the surgery with early symptoms of influenza on March 15th, when the temperature was taken and found to be 100.2°. 0.5 c.cm. S.U.P. 36 was injected into the deltoid muscle, and she was sent home to bed, where she stayed all the next day. On March 17th she was feeling better, and attended at the surgery the next day quite well. She only complained of the arm being "a little stiff for twenty-four hours." No second injection was given.

Case 40a.—Miss E. S., aged 25. Typical influenza. Temperature 100°, headache severe, cough troublesome, and muscular pains. 0.5 c.cm. S.U.P. 36 injected into the deltoid muscle. The next day the temperature was normal and all symptoms with the exception of the cough had disappeared. Complete recovery in five days with no second injection.

Case 41a.—Mr. E. S., aged 35. Typical influenza. Temperature 101°. 0.5 c.cm. S.U.P. 36 injected into the gluteus medius. Next day the temperature was normal, but the patient was kept in bed. The day following the patient got up and went out, resuming his work on the fourth day after onset. No second injection was given.

Case 42a.—Myself. Early influenza. Felt symptoms of influenza coming on all day, and at 6 p.m. temperature was found to be 100.6°. At 7 p.m. I injected 0.75 c.cm. S.U.P. 36 into one of my thigh muscles as the initial dose and went to bed an hour later. Next morning my temperature was normal and I felt much better. Stayed in the house that day and resumed my work the following morning, forty hours after the injection, feeling perfectly well.

It is important to emphasize here that all the cases injected were definitely influenza, showing the clinical symptoms already described, and that no cases of "severe colds" were included. The injected cases, as a matter of fact, were mostly of a rather more severe nature than those not injected.

Case 9a is of special interest on account of the catarrh present having existed for some time prior to the onset of the influenza. My observations in this case led me to suspect that the injection of S.U.P. 36 might have influenced the catarrh apart from the acute condition, and that S.U.P. 36 might therefore hold out possibilities for the treatment of cases of purely chronic nasal catarrh. I have tried the treatment in several other cases, and the results so far are very encouraging.

Summary of Conclusions Arrived At.

1. That the injection of S.U.P. 36 should be made at the earliest possible moment when once symptoms point definitely to influenza.

2. That in the early uncomplicated case the initial dose should be 0.5 c.cm.

3. That in severe early cases, cases of more than twelve hours' standing, and cases presenting such complications as tonsillitis or bronchitis, the initial dose should be 0.75 c.cm.

4. That these doses need only be repeated on the fourth day after the initial dose if symptoms have persisted until that time, and that there is no advantage whatever in repeating the injection when symptoms have subsided.

5. That although the gluteus medius muscle is the site of choice, the injections can quite well be made in other muscles. This is a very much more important matter in

general practice than might be supposed, especially in view of the importance of making the injection "then and there" at the earliest possible moment.

6. That the early initial dose completely aborts the attack in nearly every case, and that therefore if the treatment be used in influenza epidemics on a wholesale scale and early enough it is the most valuable agent that we at present have discovered for combating these epidemics.

7. That treatment administered at later stages, providing that the attack has not existed for more than forty-eight hours, considerably shortens the duration of the disease.

8. That although my present series of cases is too small to show whether the liability to complications is reduced, I certainly think that this will be proved to be the case.

THE HINTON TEST FOR SYPHILIS.

BY

T. E. OSMOND, M.B.,

PATHOLOGIST, VENEREAL DISEASES DEPARTMENT, ST. THOMAS'S HOSPITAL.

THE Hinton test for syphilis[1] has attracted so much attention, more especially in America, that a trial of its value appeared to be a subject of considerable interest. The test is essentially an agglutination reaction depending on the reaction between syphilitic serum and an antigen consisting of a mixture of glycerol, cholesterol, and extract of beef muscle; it is simple to perform, and, what is even more important, easy to read. A satisfactory antigen having been obtained, all that is necessary is to mix varying amounts of inactivated serum with a fixed amount of antigen and incubate for sixteen hours at 37° C. Reading is done with the naked eye, and results are recorded according to the agglutination of particles.

For the above purpose 500 serums were submitted to the Wassermann[2] and Hinton tests. They were mostly obtained from treated cases of syphilis, but a number from untreated cases of syphilis, and cases without syphilis were included. The following figures show how far the two tests agreed.

Absolute agreement	409	458 = 91.6%
Relative agreement	49	
Disagreement	42	= 8.4%
Total cases	500	

Of the 42 cases in which there was disagreement the Wassermann test appeared to be correct in 25 and the Hinton in 17. Of the 25 cases, in 18 of treated syphilis the Wassermann reaction was positive and the Hinton negative; in 3 cases of untreated syphilis the Wassermann reaction was positive and the Hinton negative; in 2 cases without syphilis the Wassermann reaction was negative and the Hinton strongly positive; in 2 cases without syphilis the Wassermann reaction was negative and the Hinton weakly positive. Of the 17 cases, in 15 of treated syphilis the Wassermann reaction was negative and the Hinton positive; in 2 cases of untreated syphilis the Wassermann reaction was negative and the Hinton positive.

From the above it will be seen that the Hinton test gave four apparently false positive results. Two of these were only weak positives and might have been read as "doubtful." The explanation of the other two is not clear; they may have been due to errors in technique. Apart from these the agreement between the two tests was remarkably close, especially when consideration is given to the fact that a large proportion of the serums were "borderline" ones from treated cases of syphilis.

In addition to the above the opportunity was taken, when a sufficient amount of serum was available, to compare the Hinton with the Kahn[3] test, and also with the Sigma[4] test.

The Hinton and Kahn Tests Compared.

Absolute agreement	170	187 = 93%
Relative agreement	17	
Disagreement	14	= 7%
Total tests	201	

Of the 14 cases in which the two tests showed disagreement 7 were in favour of the Kahn and 7 in favour of the Hinton, as judged by the clinical history of the cases.

The Hinton and Sigma Tests Compared.

Absolute agreement	113	127 = 92.7%
Relative agreement	14	
Disagreement	10	= 7.3%
Total tests	137	

Of the 10 cases in which there was disagreement 6 were in favour of the Hinton and 4 in favour of the Sigma.

It would appear from the above that the Hinton test can claim to be the equal, at least, of the Wassermann, Kahn, and Sigma tests. It is the easiest to perform, and far easier to read than either the Kahn or Sigma test. The only difficulty is the standardization of the antigen; once this is overcome the setting up and reading of the test are simplicity itself.

I have to thank Dr. W. A. Hinton for the description of his technique and for supplying me so kindly with the antigen used in the above investigation, and also Colonel L. W. Harrison for permission to publish the results.

THE WASSERMANN REACTION AND KAHN TEST.*

BY

FRANK MARSH, M.B., B.S.LOND., M.R.C.S.

ON May 24th, 1928, the Kahn test was adopted as routine, to be performed in parallel with the Wassermann test on all blood specimens received in sufficient quantity. Up to December 31st, 1928, some 169 specimens had been dealt with in this fashion. Of these, 108 were negative by both tests, one specimen was positive by both tests, and 26 were strongly positive by both tests, using the nomenclature of the League of Nations Health Committee. The two reactions can be said to have been in complete agreement in 135 specimens out of 169, or 80 per cent. So far there has not been an instance of a strongly positive Wassermann reaction occurring with a negative Kahn test in the same specimen, although a strongly positive Wassermann reaction has coincided with a "weakly positive" Kahn test on two occasions. On one occasion the Wassermann reaction was negative and the coincident Kahn test strongly positive; this occurred in a blood specimen from a man with a remarkable fibrous hypertrophy of his upper and lower gums, a portion of which swelling, on section, showed typical syphilitic granulation tissue.

In the 34 cases not showing complete agreement in this series, the Wassermann reaction and the Kahn test were roughly in agreement.

Of 11 cases, the Wassermann test was negative and the Kahn weakly positive in 3; the Wassermann test being weakly positive and the Kahn negative in 8.

Discrepancies, when they occurred, were of degree rather than direct opposition.

Slight discrepancies occurred in 9 cases, the Wassermann reaction being weakly positive and the Kahn positive in 2; the Wassermann positive and the Kahn strongly positive in 3; while the Wassermann test was strongly positive and the Kahn test weakly positive in the remaining 4.

Marked discrepancies occurred in 14 cases. Of these, the Wassermann reaction was negative and the Kahn positive in 3; the Wassermann was positive and the Kahn negative in 10; the remaining case showing a negative Wassermann and a strongly positive Kahn reaction.

The two reactions can be said to have been in nearly complete agreement in 146 out of 169 specimens, or roughly 86.4 per cent.

Of the 13.6 per cent. of discrepancies, only one (0.6 per cent.) was of supreme importance (Wassermann negative, Kahn strongly positive). The remaining 13 per cent. contains 13 instances of contradiction (Wassermann positive,

* A report of work done in the Pathological Laboratory of the Anglo-Persian Oil Company's Hospital at Masjid-i-Sulaiman, Persia. Published by permission of the Chief Medical Officer.

Kahn negative, and vice versa)—a percentage of 7.8. The remaining 5.2 per cent. were discrepancies of degree only, both reactions being positive, but one or the other strongly so.

To sum up, one may say that 91.6 per cent. of the tests roughly agree and 8.4 per cent. are contradictory as performed by the technique at present in use. It was found that in treated cases there was a tendency in blood specimens for the Wassermann to become negative sooner than the Kahn test—possibly owing to the Wassermann being slightly less sensitive; but in untreated cases one formed the impression that the Kahn test gave fewer false positives. Both reactions occasionally fail when the clinical signs of syphilis are fairly clear-cut.

In October a specimen of blood from an out-patient with very large hard dry perianal condylomata was examined and found negative by both the Kahn and Wassermann reactions. This patient was examined in the laboratory with a view to the detection of *Sp. pallida* in his lesions by the dark-ground method; also the possibility of infection with *S. mansoni* was investigated, with entirely negative results in each case. After biopsy by Dr. Davies a portion of a condyloma was submitted to microscopical examination in section and showed gummatous tissue. Another section treated by the method of Levaditi failed to show any spironemas, but the evidence of the histological structure of the fragment was conclusive.

The problem of a satisfactory Wassermann antigen has been a great source of speculation and experiment. The antigens in common use in English laboratories are a simple alcoholic extract of fresh heart muscle (bovine or human), and such antigens keep in the English climate in a cold chamber for many years. A small supply of English-made antigen was brought out to Persia by the pathologist, but, in the atmosphere of Masjid-i-Sulaiman, rapidly developed anticomplementary properties and became unfit for use.

Antigen prepared in Persia from bullock hearts and guinea-pig hearts by a variety of methods (Mackintosh and Fildes, modified Kahn, Neyman and Gager, Park and Williams) all became unfit for use after keeping on ice for two or three months in the summer. Even the Kahn antigen suddenly failed five months after the date of manufacture. The antigen elaborated by Kolmer is now being constructed and experimented with, and it is hoped that this antigen may solve many of the problems connected with the manufacture of a sensitive antigen with good keeping properties. Many of the discrepancies between the results of the Wassermann reaction and the Kahn test are probably due to defects of the antigen used. A supply of pipettes graduated in one-thousandths of a cubic centimetre are now on the way out, and will greatly assist the technician in performing the numerous and very accurate measurements of minute quantities of liquid that are such a feature of the Kahn test.

The difficulties with the supply of complement that were so acute last year were in a great measure overcome by the adoption of the routine of storing complement, frozen hard, in a test tube surrounded with a freezing mixture in a thermos flask. This year forty-six Wassermann reactions were performed with the blood from one guinea-pig; last year it was seldom that more than twelve Wassermann reactions could be performed with the blood from one guinea-pig.

In conclusion, it may be stated that, at its present stage of development, the Kahn test cannot replace the Wassermann reaction, but the adjuvant value of the tests when performed in parallel on all blood specimens is very high indeed.

ANTHRAX IN A 15 MONTHS OLD BABY.

BY

ALBERT E. HODGSON, M.D., D.P.H.,

SENIOR MEDICAL OFFICER, CITY HOSPITALS, FAZAKERLEY, LIVERPOOL.

The case here recorded is of interest from various points of view, among others the age of the patient and the probable source of infection. Incidentally, an added interest arises from the fact that the father of this baby was himself a patient of mine suffering from anthrax, from which he recovered, eight months ago.

L. E. W., aged 15 months, was admitted to the City Hospital, Fazakerley, on May 9th, 1929, suffering from cutaneous anthrax. The infection had taken place on the front of the left forearm, one inch below the flexure of the elbow-joint. On arrival at the hospital with the baby the mother said that she had noticed the red "spot" on the arm five days before, but had not then thought it a cause for alarm. By May 9th, however, the "spot" had become much more angry, the arm had swollen, and the child was ill and distressed. The mother took it to the doctor, who at once suspected the nature of the condition, especially as anthrax is at all times a present danger in the district (Runcorn, Cheshire), and also as the father works in a local tannery. A film showed the presence of *B. anthracis*, and the patient was immediately sent to hospital.

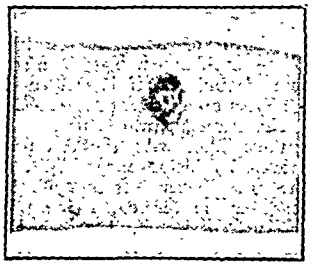

FIG. 1.

FIG. 2.

FIG. 1.—Photograph taken on May 10th, showing the vesiculated lesion. The swelling of the arm is evident.

FIG. 2.—Photograph taken on May 17th, showing the ulcer after the shedding of the necrotic slough, as well as the abatement of the swelling.

When the child was admitted the local appearance was typical. The arm was much swollen, red, and indurated from three inches above the elbow-joint to well below the middle of the forearm. The axillary lymphatic glands were not unduly enlarged or tender. Characteristically, the swollen arm was not as painful to touch as the swelling would lead one to expect. The lesion showed a small dark brown centre about one-fourth of an inch in diameter, surrounded by a ring of angry vesicles, the whole covering an area rather larger than that of a shilling. Film and culture confirmed the presence of the anthrax bacillus.

Owing to the plumpness of the child the intravenous route for the injection of serum was not practicable, and accordingly the intramuscular method was chosen. A dose of 50 c.cm. anti-anthrax serum (Parke, Davis and Co.) was given immediately. The infected area and arm were treated with eusol fomentations. No excision was made. A like amount of serum was given the next day and on the three succeeding days, making in all five injections of 50 c.cm. each.

The temperature and pulse, which hovered about 98.8° to 99.8° F. and 120 to 130 respectively for five days, became normal on the sixth. For the first two days the local inflammation increased, and the arm became much more swollen and indurated. On the third day a definite decrease of inflammation and swelling commenced, and by seven days from the first injection the arm was no longer swollen except for a very limited zone about the slough at the point of infection. From the third day the baby appeared well and took its feeds readily.

The child made uneventful progress except for the incidence of a severe serum rash of urticocrythematous type which appeared on May 25th, and persisted for five days. The wound gave negative swabs from May 23rd onwards. Healing was normal, and when the baby was discharged a well-formed circular scar only remained, with no evidence of adherence to the tissues underneath.

I have not been able to find on record any case of anthrax in so young a patient. The source of infection almost certainly originated in the dust carried on the father's clothes from his work. The response to anti-anthrax serum injected intramuscularly, without excision of the "malignant pustule," is gratifying, though elsewhere[1] I have preferred the intravenous method, and almost invariably still rely upon it. In this instance it is probable that a more rapid checking of the inflammation would have been produced had the latter mode been feasible.

I desire to thank Dr. Claude Rundle, medical superintendent of the City Hospitals and Sanatorium, Fazakerley, for his kind permission to publish the case.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

FRACTURE OF PATELLA WITH ATYPICAL SIGNS AND SYMPTOMS.

ON May 21st of this year A. W., when dirt track racing, crashed into a fence. His knee struck the fence and the gear lever of his machine. At this stage all the combatants fell, and the race had to be re-run from the beginning; it was won by A. W.

He did not notice any pain during the race, but nearly fainted on its termination. On the following day he got about with the aid of crutches, and re-started racing in ten days, which, however, gave him some pain. On July 10th he was sent to me by a colleague for an *x*-ray examination because of pain on pressure exerted from above downwards on the antero-internal aspect of the knee. When seen by me I was able to elicit the above sign in

the region of the internal semilunar cartilage. Direct backward pressure, however, did not cause pain. He could extend and flex the knee to the full extent without causing any pain. There was a moderate amount of fluid present in the joint. Pressure exerted on the patella from all directions did not cause pain. The skiagrams show a Y-shaped fracture of the patella.

The case is of interest because of the very small amount of pain and disability caused by the fracture, and because of the impossibility of diagnosing the condition other than by an *x*-ray examination.

TREATMENT OF ECLAMPSIA BY SPINAL ANAESTHESIA.

I THINK it worth while recording the following details of a case of eclampsia which was successfully treated by spinal anaesthesia on the lines suggested by Dr. R. H. Paramore at the meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on April 20th, 1928, and published in the *Proceedings* of that Society (1928, vol. xxi, p. 70).

A young primipara, in the seventh month of her pregnancy, was suddenly seized with convulsions on April 29th after a day of "spring cleaning." I found her at 8 p.m. in the throes of severe eclampsia, without any intermission of the fits and quite unconscious; I injected 1/4 grain morphine without effect. In response to an urgent message Dr. Paramore came, sending word in advance for me to administer chloroform; I did so, but until deep anaesthesia was reached the fits continued. On his arrival Dr. Paramore prepared the patient and administered tropacocaine by lumbar puncture. The effect was immediate, the fits at once subsiding, nor, when the effect of the chloroform had passed off, was there any recurrence. I saw the patient in violent convulsions at 8 o'clock; by 10 o'clock she was quiet and could be left to the nurse, one slight fit occurring just after we left. The patient went to full term without any further relapse, and was delivered naturally, on June 20th, of a male child 7¼ lb. in weight, which lived eight days.

The immediate after-effects of the eclamptic seizure were muscular pains all over the back, headache, and noises in the head; these had all passed off by the end of the week. The more remote effect was a momentary feeling of losing herself, or as the patient puts it, "I don't know where I am." This was first apparent during the puerperium, and she complained of it again on July 8th; otherwise she is quite well.

This case may be contrasted with another of equal severity which occurred just fourteen years previously, my first case of eclampsia after coming to Rugby. (Two cases which occurred between I sent to hospital; one patient died, but the other, a mild case, recovered after a prolonged illness.) In the first case and the most recent one the patients were of the same physical type; both were strong and rather stout young women late in their first pregnancy, and both were quite well until, after some extra bodily strain, they were seized with convulsions.

On April 21st, 1915, a woman far on in her first pregnancy walked to the railway station, which is about two miles from her home, and was seized with her first convulsion; she was removed to hospital and later to the infirmary, where she regained consciousness. She returned to her home, but the fits immediately recurred and continued until she aborted three days later, being delivered of a dead child. The treatment in this case was hot air, pilocarpine, and, later, on the advice of the late Dr. Clement Dukes, injections of morphine at repeated intervals. At no time could it be said that the treatment was either effective or satisfactory, the fits continuing until delivery. After delivery it was found that the patient was mentally affected, and, since she gradually became violent, she was removed to the asylum on April 29th. She remained there for three and a half weeks, when she recovered and was discharged. She has since remained quite well.

I think the contrast between these two cases is too marked to be ignored; whatever the theories as to the cause of eclampsia may be, Dr. Paramore's method of treatment by spinal anaesthesia is so immediately effective that it should be made a note of.

IONIZED SILVER IN THE TREATMENT OF BURNS.

DR. KURT HULDSCHINSKY, in a paper read at the meeting of the Berlin Society for Internal Medicine and Paediatrics on July 9th, 1928,[1] described a treatment of eczema in children by what he called the "Uvag" or ultra-violet argentum method. I have lately been using this method for burns with such good result that it seems worth description.

Silver nitrate in a 1 to 5 per cent. solution is sprayed or painted on the area affected by the burn. An exposure of one to five minutes is then given with a mercury vapour or tungsten arc lamp at a distance of six to twenty inches, the varying limits being given to allow for the factors of the age of the patient, the size of the burn, efficiency of the lamp, etc. In the absence of an artificial source of ultra-violet rays an exposure to real sunlight, if it can be obtained, for half an hour produces much the same result.

The silver nitrate is ionized by the light and the silver ion combines with the cell proteins—an effect which is practically instantaneous with artificial ultra-violet light; the whole area becomes black and dry, and a shiny coagulum is formed, fixing proteins resulting from cell destruction, which, if absorbed, give rise to the toxaemia often associated with burns, and at the same time the penetration of the rays to the deeper layers is prevented, thus counteracting any possibility of over-irradiation. Rapid healing is produced in second degree burns and the pain is very much decreased. No dressings are used and the bedclothes are not allowed to touch the treated area. Another application may be given in twenty-four to thirty-six hours if required.

In theory[2] the process is similar to the tannic acid treatment,[3] but it has the additional advantage of the peculiarly sedative action of ultra-violet rays on peripheral nerve endings as well as its bactericidal effect. Unfortunately the number of cases that I have had the opportunity of treating by this method so far has been few, but it would be interesting to hear what results are obtained from a wider application of this method, which seems a most satisfactory one.

Reports of Societies.

SOME PRINCIPLES OF THERAPEUTICS.

In the Section of Therapeutics and Pharmacology of the Royal Society of Medicine, on October 8th, the annual address from the chair was delivered by the incoming president, Dr. PHILIP HAMILL, who discoursed very briefly on "Some principles of therapeutics."

Dr. Hamill began with the remark that when drafting a scheme for dealing with any particular problem he had found it useful to consider first whether any canons of therapeutics could be formulated, and then to examine the available resources in relation to them in order to determine how far these complied with the ideal. The more accurate one's appreciation of the nature of the disorder to be treated, and of the physiological changes which had occurred, the more readily could one act with assurance *that such intervention would not be untimely or misplaced.* One of the great difficulties was the tendency to conclude that any departure from the accepted normal was in itself evil, and to set out to correct it; whereas deeper knowledge might reveal that the abnormality was but a manifestation of a compensatory mechanism, and that to counteract it would not be helpful. At the same time, he was far from suggesting that symptoms should not be treated; on the contrary, it was necessary to intervene when symptoms were in themselves distressing and called for relief. At times, indeed, very little more than this could be done.

Many of the conditions with which the medical man had to deal were the result of previous disease. Damaged organs had to be sustained and protected from further injury. A heart or kidney already damaged could not well afford to be subjected to any subinfection or intoxication. Stresses which a subject in good health could bear with little difficulty or risk might easily precipitate a breakdown in a subject already "out of repair." In a reference to substitution therapy, the speaker mentioned how the effects of atrophy or degeneration of some organs could be met by supplying a hormone which they no longer themselves liberated to an adequate extent. Brilliant examples of substitution therapy were afforded by thyroid extract and insulin in cases involving loss of function of the thyroid or the pancreas, though the cause of such loss of function was still unknown.

Methods of Dealing with Infective Processes.

In dealing with infective processes the cause of the infection should, wherever possible, be eliminated, and this in its broader aspect involved large questions of public health *administration and industrial hygiene.* In the combating of established infections, which was more closely the concern of the Section he was addressing, he mentioned the success achieved with quinine in malaria and emetine in amœbic dysentery, the organic arsenic compounds in syphilis and relapsing fever, and antimony compounds in leishmaniasis, trypanosomiasis, and bilharzia. In bacterial infections the success had not been so evident: although by means of drugs the blood could be made bactericidal to pneumococci, success in the clinical treatment of pneumonia had not been realized; mercurochrome was still on probation in the treatment of general infections; and urinary antiseptics, while they rendered the urine strongly bactericidal, had not been proved greatly to influence the duration of an attack of acute cystitis. On the other hand, the beneficial effects of sanocrysin in tuberculosis and of chaulmoogra oil in leprosy were encouraging as indicating that direct attack on bacteria in the tissues was possible. Another example of direct attack was the treatment of gonococcal cervicitis by diathermy, in which the tissues were heated above the thermal death-point of the organism but themselves remained unchanged.

Prophylactic Immunization and Serum Therapy.

If the cause of an infection could not be eliminated or directly combated, perhaps the chosen recourse was to confer or exalt immunity. In principle, prophylactic immunization against small-pox, the enteric group of diseases, and scarlet fever, on the one hand, and serum therapy on the other, were almost ideal. By the former of these methods the body was itself educated in the art of its own defence; by the latter the fruits of training and experience in others were directly transferred. Specific immunotherapy, however, though ideal in principle, fell short of requirements in practice in many respects, more particularly in the treatment of less severe ailments. The immunity was too specific—there was no mithridatum available as yet—and sometimes it was short-lived. In serum therapy, again, there was usually some delay until the nature of the infection could be recognized. For many infections immunizing agents of adequate potency had not yet been developed, so that the body had to rely on its own resources, its power to develop antibodies under stress of invasion or intoxication.

Nutrition and Elimination.

Dr. Hamill next turned to the important factors in developing and maintaining this bodily resistance. These factors were nutrition and elimination, rest, and hygienic surroundings. It was common knowledge that individuals *varied in their resistance to, and power of, combating infection,* and that those who were properly nourished and lived under hygienic conditions had powers of resistance, on the whole, greater than others less favourably circumstanced. He mentioned in this connexion the experiments of Mellanby and Green (*British Medical Journal*, 1928, ii, p. 691) on vitamin A in the dietary as a factor in producing immunity to infection. During the influenza epidemic of 1929 a London business firm placed at the disposal of its staff a preparation rich in this and other vitamins, and while the staffs of most business houses suffered severely during the epidemic the list of absentees on account of influenza or "colds" in this particular firm was quite inconsiderable. The same investigators (ibid., 1929, i, p. 984) went on to apply a severe test, administering vitamin A in massive doses to patients suffering from puerperal septicæmia; the mortality fell to zero, as compared with 90 per cent. in the same institution in previous years. No extravagant claims were made by these investigators, who were content to put forward the results so far obtained as warranting further trial of this mode of treatment. But if the observations were confirmed it would be legitimate to argue, said Dr. Hamill, that the power to overcome a virulent septicæmia was conferred by oral administration of full doses of vitamin A, and to regard as proved that not only resistance to infection but power to develop immunity were, in a measure, capable of control by dietetic means. Vitamin A was contained in milk and other dairy foods, green vegetables, and oily fish, such as the sprat and herring—forms of diet readily obtainable by the poor.

Rest as a Therapeutic Measure.

On the subject of rest, Dr. Hamill said that he spoke with trepidation, not wishing to reawaken a recent controversy on the use of hypnotic drugs. He was ready to admit that on occasions hypnotics were of the highest value, but he felt that, quite apart from the irresponsible manner in which they were taken by patients of their own accord, they were too frequently prescribed without any adequate effort to discover and rectify the causes of the symptoms, and without trial of more simple and domestic remedies. He was led from this to make a few observations on hospital planning and construction. He feared that some boards of management were not without a desire, most natural and even laudable in the case of a commercial house, to erect imposing buildings on valuable sites. To his own mind the excellent results obtained in army huts during the war appeared to justify quite a different policy, and he suggested that, instead of costly buildings in the centre of cities, less permanent structures in more open areas would admirably serve the purpose and better comply with the therapeutic ideal of rest and hygienic surroundings.

Dr. Hamill closed his brief address by stressing the fact that it was the patient's own body which in the long run effected its repairs and readjustments. The part of the therapeutist was to remove impediments and to assist the process, to ease the patient's discomfort so that he could enjoy rest, and to maintain his nutrition, circulation, and elimination until such time as he had attained immunity or equilibrium.

Reviews.

HUMAN TUBERCULOSIS OF BOVINE ORIGIN.

As medical officer of health for one of our great milk-producing counties—Somerset—Dr. WILLIAM G. SAVAGE has had the opportunity and the incentive to study the question of milk in its relation to human tuberculosis. He has made himself an authority upon the subject, and gives us the results of his investigations and experience in his latest book, *The Prevention of Human Tuberculosis of Bovine Origin*.[1] It is an easy book to review; after reading it from cover to cover, without any skipping, we may sum it up in the one word "excellent." It should have a wider circulation than most technical books; in fact, it can be read with interest by anyone, for apart from the medical profession it will be welcomed by veterinarians, agriculturists, and local government workers. Dr. Savage has a pleasant style, and, in spite of his forcibly expressed opinions, his breadth of view and tolerance show through the whole book and add weight to the lessons that he has to teach.

The book starts by admitting that the bovine tubercle bacillus causes but a small proportion of human tuberculosis—about 5 per cent. of the total annual tuberculosis death rate being due to it. But, though they are relatively small, the death rate figures are large enough to be of national importance; to them must be added the much larger figures of the non-fatal cases of illness and incapacity due to the same cause, and it must be remembered that much of this incapacity and disfigurement is lifelong. As Dr. Savage points out, there are two separate problems—the protection of human beings against tuberculous milk, and the eradication of tuberculosis among bovines. Though these are closely entangled and should be dealt with together they can be handled separately. The difficulties to be faced in attempted solutions are many, and they are mostly due to urbanization. In rural communities where milk can be produced and consumed locally the difficulties are not great; but the adequate supply of milk to large urban areas necessitates distant sources, pooling of supplies, and central redistribution. Under these conditions milk ceases to be only an important food, but becomes as well a valuable commercial product, large financial interests become involved, and the difficulties of control increase. The present pooling system makes the bacteriological examination of samples useless, for even if tubercle bacilli are found it is practically impossible to trace the culprit herd. Pasteurization will protect the public, but there are great practical difficulties attending its use, such as the cost of plant and the fact that its efficiency depends upon the personal factor. Further, though pasteurization may be protective, it does not go to the root of the problem, but rather encourages uncleanly milk production. The certified milk scheme has not been a success, probably because the method of obtaining licences is unduly cumbersome, and it means an increase in the price of milk.

The author feels that the real solution is the eradication or diminution of tuberculosis among cows. He gives interesting figures relating to the "accredited herd plan" used in America by which the herds are examined periodically at Government expense, and tuberculin reactors when found are slaughtered and the owner indemnified by the State. This is practicable in America, where tuberculin reactors are only about 5 per cent. of the bovine population, but could not be applied to this country with its 40 per cent. of reactors. Bang's separation method, used in Denmark, is also carefully examined. It is suggested that the cause of the cow being more prone to tuberculosis than the calf is the continued strain of yearly calving and perpetual unnatural milk production, coupled with the innumerable chances of massive infection in insanitary byres. One can see that the author feels keenly on this subject and that he would like to be given a free hand to deal with the cowsheds of England. Space forbids more than this brief mention of only a few of the interesting sections of a most valuable book.

ORTHOPAEDIC SURGERY.

In our review (April 14th, 1923, p. 634) of the first edition of JONES and LOVETT'S *Orthopedic Surgery*[2] we predicted that it would become the standard work on the subject in the English language. In the second edition, which has just appeared, the work is enlarged and, in many respects, improved. The place made vacant by the lamented death of Dr. R. W. Lovett has been filled by DRS. NATHANIAL ALLISON and FRANK R. OBER of Harvard, and Mr. HARRY PLATT of Manchester, whose reputations are a guarantee that the new edition will contain an adequate account of the latest advances in bone and joint surgery.

It seems inevitable that standard works should increase in size with each new edition, and this book is no exception. The net result of some omissions and many additions is an increase of 108 pages and eighty figures, and of four chapters—thirty-five instead of thirty-one. Six years' further experience has by no means modified the very conservative and cautious attitude taken by the authors of the first edition towards arthroplasty of the knee, and towards bone-fusion operations for Pott's disease in children. One of the most important additions is the chapter on osteomyelitis. References to this infection were scattered about in various chapters of the first edition, without, however, any comprehensive discussion of the disease. The new chapter is a valuable one and embodies the conclusions expressed by Mr. Platt in his opening paper of the discussion on acute haematogenous osteomyelitis at the Orthopaedic Section of the Royal Society of Medicine (*British Medical Journal*, 1928, i. p. 456). Although the acute form of this disease is nowadays not very common in this country, its effects, if it is not early recognized and treated, are so serious that a correct and up-to-date account of its etiology, pathology, and treatment is desirable in any comprehensive work on orthopaedics.

In the present edition the subject of Volkmann's ischaemic paralysis, which was very scantily noticed in the first edition, receives due consideration, and an account is given of Jepson's important experiments, which go far to explain the pathology of this malady. Dupuytren's contraction of the palmar fascia, consideration of which was altogether omitted from the first edition, is now included in chapter XXV, under "Affections of Muscles, Tendons, and Fasciae," but no fresh light is thrown on its etiology. In this edition, moreover, instead of the chapter of six pages on malunited fractures, one of twenty-five pages on fractures in general and particular has been substituted. Even this space is by no means excessive for the discussion of a subject which is becoming more and more specialized and is of such importance to patients and surgeons; for the details of various methods of treatment the surgeon must still have recourse to special monographs. Other subjects discussed are fractures of the spine, especially compression fractures, spastic paralysis and its treatment, and amputations and artificial limbs. The chapter on scoliosis, which is one of the fullest in the book, has been enlarged by descriptions of the turn-buckle plaster jacket and of the methods of measurement and correction practised by Galleazi of Milan. We still think that a much fuller index is desirable.

PATHOGENIC MICRO-ORGANISMS.

THE third edition of KOLLE and v. WASSERMANN'S *Handbook* of Pathogenic Micro-organisms[3] is appearing seriatim, the necessary consequence, perhaps, of an attempt to deal adequately with the very large number of specialized subjects which make up the science of bacteriology and which are continually being expanded by new discoveries. It is obviously impossible to deal with each separate fasciculus on its merits in a review, but, on the other hand, the shorter notice which alone is possible should not conceal the fact that this particular series constitutes a valuable

[2] *Orthopedic Surgery.* By Sir Robert Jones, Bt., K.B.E., C.B., Ch.M., F.R.C.S., F.A.C.S., and Robert W. Lovett, M.D., F.A.C.S. Second edition, revised with the collaboration of Nathanial Allison, M.D., F.A.C.S., Frank R. Ober, M.D., and Harry Platt, M.D., M.S., F.R.C.S. Oxford Medical Publications. London: Milford, Oxford University Press. 1929. (Sup. roy. 8vo, pp. xvi + 807; 782 figures. £2 12s. 6d.)

[3] *Handbuch* [illegible] u. Begründet von W. Kolle und A. v. [illegible] Auflage. Jena: G. Fischer; Berlin und [illegible] 1929.

book of reference, the subject matter being well set out and generously illustrated. Whenever it is possible coloured plates are employed, and special care has obviously been taken in their production. References to the parts already published have appeared in several previous issues of the *Journal*. We have recently received six further fascicuti. The first of these, Part 31 of vol. i, deals with non-specific immunization, and the experimental investigation of tumours from the standpoint of infection and immunity. The respective authors are Professors W. Weichardt of Erlangen and W. Caspari of Frankfurt. In Part 35 of vol. ii Professor M. Knorr of Munich discusses the bactericidal and bacteriolytic substances in the blood; the haemolytic and complement-fixing elements are described by Professor H. Sachs of Heidelberg, while Professor F. Neufeld of Berlin deals with bacteriotropin and opsonin. In each instance the present state of knowledge and the current views held are set out lucidly though in considerable detail. Part 33 of vol. vii is devoted entirely to relapsing fever, and the author, Professor P. Muhlens of Hamburg, has prepared what is in effect a monograph embodying a useful epitome of our present knowledge: the coloured plates here are particularly good. For Part 32 of vol. viii Professor V. Jollos of Cairo is largely responsible; he contributes articles on intestinal flagellates and infusoria in the human being, and also a useful note on coccidiosis. Professor W. H. Hoffmann of Havana supplies an article on yellow fever, summing up the available information in an interesting account. There is also a well-illustrated and comprehensive description by Dr. B. Lipschütz of Vienna of the chlamydozoa and their relation to various infections. Part 34 of vol. ix deals with the principles and practice of microscopical examination, the cultivation of micro-organisms, and special procedures such as their enumeration. The authors concerned are Professors H. Reichenbach of Göttingen, W. Scheffer of Berlin, M. Berek of Wetzlar, W. Busson of Vienna, M. Ficker of Berlin, G. Giemsa of Hamburg, W. Rosenthal of Göttingen, G. Joannović of Belgrade, and E. Gildemeister of Berlin. Part 30 of vol. x includes illustrated articles on plating and the preparation of pure cultures; there are also practical notes on the investigation of anaerobes. The authors are Professor E. Pribram of Chicago and Drs. H. Lubinski of Breslau, J. Zeissler of Altona, and W. Klein of St. Goarshausen. The total value of this series is certainly very great, and it is undoubtedly convenient to be able to obtain special monographs on the various subjects, particularly when, as in this instance, each one is so carefully prepared.

THE AMINO-ACIDS.

THE production of the "handbuch" has hitherto remained almost the prerogative of Germany, a prerogative which we have been mostly willing to yield to a nation that at some points is admittedly more painstaking and industrious than ourselves; but the increasing volume of work which, coming from both sides of the Atlantic, is reported in English, has now almost forced upon us the necessity of producing something of the kind for ourselves. *The Biochemistry of the Amino Acids*,[1] by H. H. MITCHELL and T. S. HAMILTON, deals, it is true, with a single phase of a subject and not with the whole; but in completeness it certainly rivals anything that the Germans have produced, while its avowed limits make it less unwieldy and give more scope for critical treatment.

The authors' purpose in the opening chapters is to describe the chemistry of the different known amino-acids, the means by which they can be identified and estimated, and the chief methods by which they are separated. The descriptions are accompanied by a very full bibliography, and the matter is brought up to date as far as is reasonably possible, so that the book should prove of the greatest assistance to those who are engaged in advanced teaching and in laboratory work. The later chapters are constructed on an equally satisfactory plan. We may take as an example that on digestion and absorption. Except, perhaps, for the omission of the more recent papers of Waldschmidt-Leitz, the survey is thorough and complete; nor have the authors hesitated to discuss problems such as the significance of intestinal putrefaction and its possible relationship to "auto-intoxication." In the treatment of such difficult questions as endogenous metabolism and the specific dynamic action of foodstuffs, we are struck by the fairness and the clarity with which the evidence is presented, even if we do not always find ourselves in agreement with the final conclusion. A valuable feature of the book is the chapter on "Special phases of amino-acid metabolism," which is, in effect, a discussion of the relationships and physiological and chemical properties of such substances as histamine, thyroxin, glutathione, and adrenaline. Finally, there is a critical discussion of the nutritive value of proteins.

Naturally, the matter is approached from the standpoint of the laboratory worker dealing with experimental animals, rather than from that of the clinician dealing with patients. Current experimental methods are discussed and certain common practices are criticized. The interesting question of the possibility of using non-protein nitrogenous bodies—for example, urea—as a source of nitrogen is discussed at some length, and mention is made of the experiments on these lines done in Germany during the war. We could wish that the question of "optimal" and "adequate" nutrition had been pursued, and that the authors had discussed more fully the question whether, by adjusting the quantity and quality of the ration, an altogether supernormal race of organisms could be produced. It seems at least probable that both fertility and resistance to disease can be increased by special dietary measures, though it is true that the substances concerned seem to fall into the class of "accessory substances" rather than into that of proteins. Perhaps enough has been said to make it clear that the book is in no sense one of "applied" science. It necessarily contains much material of value to practical medicine, since it deals with one of the sciences upon which modern medicine is based; it is written, however, from the standpoint of the experimentalist, and the clinician will have to find and interpret for himself the matter which lends itself to direct application.

[1] *The Biochemistry of the Amino Acids*. By H. H. Mitchell and T. S. Hamilton. American Chemical Society Monograph Series. New York: The Chemical Catalog Co., Inc. 1929. (Med. 8vo, pp. 619; 18 figures. 9.50 dollars.)

THE RADIOLOGY OF TUBERCULOUS CAVITIES.

THE clinical investigation and radiology of tuberculous cavities,[2] by Dr. JACQUEROD of Leysin, a book of fourteen pages, which are followed by about eighty radiographs (upon twenty-four plates) of the highest degree of technical excellence, and beautifully reproduced, adds considerably to our knowledge of the course of cavity formation in cases of pulmonary tuberculosis. The author for over twenty years has been collecting material in the shape of cases which have been watched for many years, and in which a long series of radiographic examinations has been made. He describes cavities as of three degrees. (1) In those of the first degree the radiographic shadow is a relatively slightly marked ring, the interior of which is not completely clear. These are found in cases in which there is no expectoration, and they represent the first phase of a breaking-down area. (2) In cavities of the second degree there is a clearly defined ring shadow with the space inside clear. The ring shadow is caused by thickened pulmonary tissue containing tubercle bacilli, and the sputum also contains bacilli. (3) In those of the third degree there is a dense circular shadow of large dimension, the walls of which are of fibrous tissue. At the same time, many cases show ring shadows passing from one degree into another. The author holds that, apart from rare exceptions, all radiographic circular shadows, whether in the midst of normal lung or in the midst of an area of infiltrated lung, are tuberculous cavities. He discusses the reasons for coming to this conclusion, describes certain rare exceptions and their causes, and how to arrive at a definite differential diagnosis. Another very important part of this monograph is devoted to the question of the disappearance of

[2] *Spéléologie Pulmonaire: Etude Clinique et Radiologique des Cavernes Tuberculeuses*. Par Dr. Jacquerod. Paris: Masson et Cie. 1928. (9 × 12½, pp. 14; 24 plates, 81 figures. 30 fr.)

these cavities, and how this is brought about. On this point, again, the author is very definite, and his conclusions are backed up by cases in which a series of radiographs has been taken at intervals which often spread over some years.

After a brief introduction the material is divided into a series of short chapters. These deal successively with the pathological anatomy of pulmonary cavities, their frequency, their mode of formation, the question of differential diagnosis, the processes of cure, general considerations in treatment, and, finally, the conclusions arrived at. Then come the magnificent and striking radiographs already alluded to, each having a short explanatory note attached, and bearing witness to the truth of the author's conclusions. He writes in a style which even a moderate French scholar can follow easily, and his book is entirely free from padding. The volume is a valuable contribution to the literature of the subject, interesting and instructive alike to those concerned with pulmonary tuberculosis and to radiologists.

IN PRAISE OF MEDICINE.

DR. E. RIST, physician to the Laennec Hospital in Paris, has done well to publish in book form seven essays, of which the first, What is Medicine?[6] provides the title. Four of these essays have previously appeared in French journals; and though their titles suggest that the ground covered is comparatively wide (for they deal with the diagnosis of diseases of the chest before the invention of percussion and auscultation, the early stages of percussion, science and art in medicine, some moral responsibilities of the doctor, and the Hippocratic Oath), the same *motif* underlies them all—namely, a defence of the medical profession against its more serious and violent critics. The earliest of these essays in point of time, that on the progress of medicine, appeared in an ephemeral paper, *Pages libres*, in 1904, as a counterblast to an article in the previous number of that publication, which endorsed the derogatory opinions of a Russian medical man about the evolution of his profession. This essay has not been altered, as the views therein expressed still represent the author's faith after twenty-five years of further experience. Believing firmly in the value of a knowledge of the history of medicine, he sets out the state of medicine before the introduction of percussion and auscultation, and discusses the lessons to be learnt from this survey. It appears that in spite of early references to pleurisy, intrathoracic affections were not recognized, and even a century after Harvey there were the most fantastic ideas about the pulse—every viscus except the heart having a characteristic pulse ascribed to it. In discussing the familiar problem whether medicine is an art or a science, Dr. Rist gives due recognition to the value of empirical observations to the art of medicine, and, starting from the time of Edward Jenner and Laennec, traces the gradual development of scientific medicine. The essay on the early stages of percussion contains some interesting personal details about Auenbrugger, including an explanation of the mistaken spelling of his name with a *v* instead of a *u* in French literature, and embodies references to a certain number of errors in Corvisart's translation of the *Novum Inventum*. The earlier translation of Auenbrugger's classic by P. Rozière de la Chassagne, bound up with his *Manuel des pulmoniques*, is extremely rare, only one copy in Paris being known. Both in the first essay and in the last, that on the Hippocratic Oath, the wide influence of medicine on human affairs is well described, and the reader will agree that the author of these well-written essays ably justifies his faith in the value of the medical profession.

NOTES ON BOOKS.

MR. W. STUART-LOW'S little handbook on the care of the nose and throat,[7] first published ten years ago, has reached its second edition. The purpose of the book is the same as stated in the preface to the first edition—namely, to make it clear that the care of the nose and throat is worth while, that the necessity for this is urgent, and that this can be easily and simply accomplished. "A healthy nose," the author states, "is an item of physical capital which renders one almost completely immune from many of the diseases which tend to thrive under the vagaries of our climate." So many of Mr. Stuart-Low's readers having asked why the ear was not incorporated in the first edition, he has now added to this second edition a few chapters devoted to the ear, and indicated this fact in the title.

DR. MAURICE PARMELEE'S work on *Nudity in Modern Life*[8] contains an enthusiastic plea on behalf of the *Nacktkultur* movement which is prevalent in Germany and Scandinavia. While admitting that gymnosophy is not a panacea for all human and social evils, Dr. Parmelee claims that it aids naturally in bringing mankind close to nature, in promoting more genuine relations between the sexes, and in rearing the young. He maintains in particular that while gymnosophy is not associated with any particular dietetic reform, it will inevitably lead to a more hygienic dieting, and will destroy the craving for stimulants and sedatives caused by the nerve-racking life of modern civilization. The text is accompanied by a number of rather amateurish photographs illustrating the activities of those who practise this cult.

We have received the third volume[9] of the proceedings of Professor G. MARAÑÓN'S clinic at the General Hospital at Madrid for the period October, 1927, to October, 1928. The work contains brief accounts of clinical cases given by Professor Marañón or his assistants, statistics of the cases admitted in the course of the year, and a list of publications emanating from the clinic.

A third and revised edition of *The Writing of Medical Papers*,[10] by Mrs. MAUD H. MELLISH-WILSON, the editor of the Mayo Clinic publications, has now reached us. A favourable review of this little work appeared in our issue of March 31st, 1923 (p. 563), and we feel sure that the new edition will be welcomed by many who have occasion to seek guidance in the preparation of medical articles.

PREPARATIONS AND APPLIANCES.

AN ALKALINE CREAM.

CREMOR ALKALINUS (Messrs. Allen and Hanburys Ltd.) is a preparation for use in the intensive alkaline treatment of gastric and duodenal ulcer. The formulae for alkalis advocated by MacLean have been prepared in the form of simple creams. The standard formula contains sodium bicarbonate 2 parts, magnesium carbonate 4 parts, calcium carbonate 4 parts, and bismuth carbonate 1 part. A second formula is provided for cases in which the standard formula proves to be too laxative. This second formula contains the same ingredients, but less magnesium carbonate and more bismuth carbonate. The dose advocated is a dessertspoonful, which contains the equivalent of 30 grains of the alkaline powder recommended by Professor MacLean. The purpose of the preparation is to simplify for the patient the technique of administration of alkalis.

A BROMIDE BOUILLON.

Brosedan, or bromide bouillon, is a preparation of bromide and vegetable yeast; one teaspoonful contains 15 grains of sodium bromide. It has an agreeable flavour, and is suitable for administration in hot water or soup. When the mixture is given in salt-free soup the taste resembles that of ordinary soup containing salt. The preparation offers, therefore, a convenient and pleasant method for administering bromides to epileptics and other mental patients. The agents for this country are Messrs. Coates and Cooper, Great Tower Street, E.C.3.

EFFERVESCENT ALKALINE TABLOIDS.

"Tabloid" alkaline compound, effervescent (Messrs. Burroughs Wellcome and Co.), contains sodium and potassium bicarbonate, calcium lactophosphate, magnesium sulphate, sodium chloride, and effervescent salt. These tabloids are recommended for use in numerous forms of acidosis. They are sold in tubes of 25.

SOLUBLE PROTARGOL.

Protargol granulate (Messrs. Bayer Products Ltd.) contains one part of protargol and two parts of urea. The substance is white and granular; it is very soluble, and dissolves rapidly in cold water. The purpose of this preparation is to provide protargol in a form in which it can be easily and rapidly dissolved; three parts of the granulate are equivalent to one part of protargol. Protargol is a brand of silver proteinate containing 8.3 per cent. of silver, and is a well-known remedy for conjunctivitis, urethritis, and other infections of mucosa. The protargol granulate is prepared in a convenient form, with a cap to the bottle which serves as a measure, so that a solution of any percentage can be rapidly prepared with the minimum of trouble.

THE INTERNATIONAL CONTROL OF DANGEROUS DRUGS.

BY

HILDA CLARK, M.B., B.S.Lond.

The report of the Opium Advisory Committee of the League of Nations to the Assembly this year, which was described in the *British Medical Journal* of September 28th (p. 589) and October 5th (p. 626), was presented to a somewhat pessimistic gathering. It is the Fifth, or "Humanitarian," Committee which always considers this annual report, and its members, both new and old, had reason to be depressed at the small progress which has been made in stopping the illicit traffic in narcotic drugs of addiction. This discontent was voiced by M. Parra-Perez of Venezuela, who asked for an inquiry into the reasons why States had not succeeded in limiting the manufacture of such drugs. The South American Republics suffer very severely from the growth of the drug habit and the difficulty of preventing smuggling. M. Parra-Perez believed that the traffic was actually increasing, and claimed that it was generally admitted that it can only be checked by limitations of manufacture. He pointed out that the Health Committee had been able to determine the quantities necessary for medical use, but that no measures had yet been attempted to limit manufacturers to these quantities. He suggested that the Advisory Committee did not include enough representatives of what are called the "victim" States—who do not manufacture themselves but suffer from the increase of drug habits, which are having a terrible effect on the physical and moral state of their people.

The Italian delegate, M. Sardi, strongly emphasized the urgency of restricting and rationing manufacturers, and pointed out that schemes for this purpose had been brought forward by his own Government and by that of the United States, but that both had been rejected. He proposed a resolution asking the Advisory Committee to take the matter up seriously.

It was explained in the discussion that States were still expecting the indirect effect of the general system of export and import licences upon manufacturers to bring about the limitation which is accepted as a principle in the 1925 Convention.

The Japanese delegate gave the welcome news that his Government was trying to limit manufacture, and the Spanish, Hungarian, and Serbian delegates each spoke of measures taken in their respective countries to strengthen the control of this traffic.

Then came a surprise which changed the atmosphere of the conference. The French delegate, M. Pernot, announced that his Government, realizing that no really effective result could be obtained without direct limitation of manufacture, had prepared a measure, which would come into force within a few days, by which French manufacturers would only be able to handle the raw material and manufacture these drugs within the limits determined by a Ministerial decree. Other measures had also been taken to bring into force a strict licensing system, and no permit would ever be given to any person who had been convicted of illicit trading in any country. Further, a special Narcotics Bureau had been set up in order to combat illicit traffic in every possible way. M. Pernot pointed out that French internal legislation had been adequate to prevent the spread of drug addiction in the country, and the spirit in which the French Government had acted in taking the measures he had described was one of purely international co-operation.

This speech brought new hope and life into the discussion. A French firm was one of the four whose products were found in enormous quantities in the illicit trade when the Dutch Government made public last year the dealings of the Naarden firm, and there had been no indication up to this meeting of the Assembly whether any of the four countries to which these firms belonged intended to take adequate measures to prevent the recurrence of such leakage. The French delegate's speech showed that at least one of the manufacturing countries which had opposed direct limitation had come to realize that it was necessary, and in the course of a later session the delegate of the Netherlands, another manufacturing country, after explaining that he still did not think direct limitation necessary, announced that his Government would now be prepared to consider any practical proposal put forward.

Mr. Noel Baker, on behalf of the British delegation, promptly took advantage of this change in the atmosphere. He reminded the Committee that the British Government had put forward a proposal for direct limitation of manufacture in 1924 in the course of the preparation of the Convention, but that owing to the opposition of other manufacturing countries it had not been possible to include it. In a very able and convincing speech, he emphasized that national measures alone would not be effective without an international agreement as to the quota to be manufactured by each country of the total amount estimated to be needed for medical and scientific purposes. He put forward a draft resolution in which the Assembly would recommend the Council to "invite the Governments of the countries in which morphine, heroin, or cocaine are manufactured to confer together as to the possibility of arriving at an agreement as to the total amount of each of those drugs to be manufactured annually and as to the quota of that amount to be manufactured by each of those countries."

Mr. Baker also laid great emphasis on the urgency of all States ratifying the 1925 Convention and carrying out its provisions, and throughout the discussions, which lasted through six sessions of the Committee, one felt that, owing to the feeling that a definite attempt to limit manufacture would make the success of control more likely, the plea to States to carry out the other measures of control was meeting with more response than ever before. Among the speakers who followed, the German and Swiss delegates, representing the other manufacturing countries whose drugs have been found in large quantities in illicit trade, assured the Committee that their Governments would give favourable consideration to the British proposal.

There is not space to consider in detail the greater part of the discussion that followed. Some suspicion of the Advisory Committee was shown because it consists mainly of representatives of countries which manufacture drugs, and half of its members have not yet ratified the Convention of 1925. A number of other important proposals were considered and adopted in the final report to the Assembly, but the chief debate was on the best procedure to secure an effective plan for the limitation of manufacture. The Italian delegate insisted with great force that the conference proposed by the British should not be of manufacturing countries only, but should include representatives of "consuming" countries, and should be under the direct auspices of the League. The Chinese delegate also pressed for the inclusion of non-manufacturing States, because otherwise he felt that the temptation to the manufacturers to keep a margin above the medical needs would be too great and public opinion in the States which suffer most from the drug habit would not be satisfied. It was the latter States which were vitally affected.

Mr. Noel Baker, who had already proposed that there should be further representatives of the "consuming" countries on the Advisory Committee, agreed that they should also be represented in the conference on limitation of manufacture, in equal numbers with the representatives of manufacturing countries.

Finally a long resolution was agreed on, presented to the Assembly, and adopted. The important points are that the Assembly asks the Advisory Committee to prepare plans for the limitation of the manufacture of the drugs mentioned in paragraphs (*b*), (*c*), and (*g*) of Act 4 of the Convention

of Geneva by international agreement, regard being had to world requirements for medical and scientific purposes, and the means of preventing an increase in price which would lead to the establishment of new factories in countries which are not at present manufacturing countries. The Committee's report is to be presented to the Council, "which will decide on the convening of a conference of the Governments of countries where drugs are manufactured and the principal 'consuming' countries in a number not exceeding that of the manufacturing countries, and whether certain experts proposed by the Opium and Health Committees should be included."

This conference will evidently be of considerable interest to the medical profession. The drugs which are to be limited are those which are scheduled as dangerously habit-forming, but the question will certainly arise whether it is possible to have adequate control of these without some provision to keep track of those products of opium, such as codeine, which are not found to be dangerous. Obviously a manufacturer can profess to be manufacturing codeine when he is really buying it in the open market and using the opium he obtains for this purpose to manufacture additional supplies of morphine.

Manufacturers who are above suspicion will feel aggrieved if they suspect that others are making profit in this way. The question of State monopoly will also doubtless be considered, and many feel that it will prove to be the best solution.

INDUSTRIAL FACTORS IN THE PRODUCTION OF TUBERCULOSIS.

ADDRESS BY SIR THOMAS OLIVER.

ONE of the events of the fifteenth annual conference of the National Association for the Prevention of Tuberculosis, which has been taking place during this week at Newcastle-upon-Tyne, was a discussion on the factors that produce adult pulmonary tuberculosis.

In an opening address, in which he approached this question from the industrial side, Sir THOMAS OLIVER, Vice-Chancellor of Durham University, said that while occupation as such could not cause tuberculosis—unless in the case of direct infection of a wound—it could favour the development of the disease by locally predisposing the pulmonary soil for the reception of the organism, and also by reducing the individual resistance. Moisture and dust were the media for the conveyance of bacilli, but the number of tubercle bacilli thrown off during coughing, apart from expectoration, was smaller than might be expected. Experience showed that where tuberculous workmen were employed, so long as spittoons containing disinfecting fluid were provided and used their fellow-workmen remained free. It was when a careless phthisical workman spat indiscriminately on the floor, and the expectoration, having dried, was raised from the floor with the fine dust, that there was danger. As direct sunlight was hostile to the organism, factories in which dusty occupations were followed should have large windows so placed as to allow the workrooms to be flooded with sunlight, even if, during the summer months, it was necessary to make them temporarily opaque.

After mentioning bodily conditions, such as fatigue, exposure, and lack of nourishment, which lowered the barriers of resistance, Sir Thomas Oliver spoke at length on dust, especially dust of hard stone, which, when inhaled, seriously injured the lungs. The particles evolved from a rock during dry machine drilling varied in size, but all had the same character of extreme hardness and comparative insolubility in the juices of the body, so that on reaching the lungs they might, if in small quantity, be engulfed and eliminated by the large scavenger cells in the pulmonary alveoli, or by means of mobile cells be carried into the lymphatics of the lungs, and, emerging from them, subsequently give rise to structural changes in the connective tissue which tended to fibrosis. The organisms of influenza and pneumonia, when operating in the lungs, could induce physical alterations of an almost similar character. On the whole, the lung with fibrosis caused by dust was harder and heavier, cut with a gritty sensation, and when incinerated showed a larger quantity of ash and was richer in silica than a fibrotic tuberculous lung.

Discussing some trades in particular, Sir Thomas Oliver mentioned the Sheffield cutlery trade. Much of the hand grinding of steel blades had been replaced by machine grinding, and natural sandstones by an artificial abrasive wheel. Great improvement had taken place in the health of the Sheffield steel grinders. In 1927 the medical officer of health for Sheffield reported that his city's death rate from tuberculosis was less than that of any other town, very considerably less than most, and that the percentage of reduction during the previous decade had been the highest of any town, much higher than the figure for England and Wales as a whole. With regard to granite cutting, Sir Thomas Oliver cited some experiences from the United States which showed that there was no particular liability to pulmonary tuberculosis so long as the concentration of granite dust remained within certain limits. There appeared to be a distinct relationship between the length of exposure to the granite dust and the prevalence and mortality rate of tuberculosis. Men following a dusty occupation and breathing orally could not but inhale the dust, the finer particles of which might reach the lungs and induce the structural changes mentioned. As the silicosis proceeded the altered structure of the lungs appeared to provide a favourable soil for the reception and multiplication of the tubercle bacillus, so that if a workman with silicosis lived for a few years he would probably succumb to tuberculosis.

In the report of the Miners' Phthisis Medical Bureau for 1928 Dr. Irvine had stated that in the gold mines of South Africa, while the number of cases of simple silicosis had in recent years decreased the infective or tuberculous type of the malady had increased, and he regarded the present method of mining, involving sprinkling with water, as largely responsible. Dr. Irvine was of opinion that water sprinkling, while it had contributed largely to a great reduction of the dust content of the mine air, had certain positive disadvantages, for even with the best of watering a residuum of very fine dust remained, for the removal of which the best means would be ventilation as if the material were a gas. A moist atmosphere formed a good vehicle for the entry into the lungs of whatever dust remained in the air, and an equally good entry for tubercle bacilli. The finest particles of dust, such as soot and coal dust, did not take up water, and here Sir Thomas Oliver described some experiments on the surface tension of these materials, which had been carried out for him by Professor W. M. Thornton of Armstrong College. It was generally held that the finest particles, when inhaled, injured a miner's lungs, but according to these experiments, even when passed through water, most of the finest particles remained dry and were not moistened at all. The particles, however, still exercised their power for harm as siliceous agents, so that their removal by ventilation would be more effective as a preventive measure than water sprinkling.

Sir Thomas Oliver also touched on trades of a lighter kind, into which less robust adolescents were drawn, such as wholesale tailoring, where a high tuberculous mortality was not entirely due to the occupation itself, but to the combined influences of faulty posture, the nature of the work, and often overheated and badly ventilated workrooms, reacting unfavourably upon individuals with inherited or acquired physical feebleness. Among laundresses there had been a notable decline in tuberculosis, owing to the fact that parcels of clothing now received preliminary disinfection, and washing was largely done by machinery. Rigid attention to cleanliness and disinfection accounted for the small incidence of the disease among hospital and sanatorium nurses. The same remark did not apply, in his experience, to sisters of religious orders; incidence of tuberculosis was high, especially amongst those who were brought into intimate association with subjects of chronic phthisis, and who spent hours in imperfectly ventilated wards and took little exercise in the open air. In a final word on injury and tuberculosis, Sir Thomas Oliver remarked that injury of itself could not cause the disease, but where patients had died shortly after a severe blow upon the chest the lung at the autopsy had been found lacerated and haemorrhagic. Had the individual survived he might subsequently have died from pulmonary tuberculosis, due either to infection by inhalation or to the activation of dormant foci.

British Medical Journal.

SATURDAY, OCTOBER 12TH, 1929.

THE INCIDENCE AND CONTROL OF MEASLES.

No student of recent vital statistics is likely to take a light view of the risks attaching to measles, which, as Sir George Newman has reminded us in his annual report for 1928 on the state of the public health, ranks second only to whooping-cough as the most fatal infectious disease of childhood. The Registrar-General's survey for the same year of death rates from the principal epidemic diseases of persons at ages under 15 provides illuminating data of the comparative mortality from measles, scarlet fever, and whooping-cough, the average figures for the period 1921–28 being respectively 422, 77, and 437 per million persons living. While, moreover, the scarlet fever figures show an *irregular but still definite tendency to decline*, and those for whooping-cough *were lower in 1928 than in* 1927, the figures for measles, though subject to *fluctuation*, remain consistently high, the rate in 1928, for example, being *considerably higher* than in the previous year. In London alone, as Dr. F. N. Kay Menzies points out in his report on the measles epidemic of 1927–28,[1] the deaths during the six months ended May 31st, 1928, numbered 1,357, as compared with 1,034 during the six months of 1925–26, also an epidemic period. This interval of two years between epidemics of measles appears to be constant in London. Outbreaks usually start in the latter part of the autumn and last about six months, during which period the ratio of immune to non-immune persons becomes high enough to withstand "infection pressure." Gradually, however, and mainly owing to new births, the proportion of susceptible children rises until, in eighteen months, the "mass immunity" once again becomes too low to withstand rapid spread of the disease. Observation of school children has shown that at least one-third of them must be susceptible before an outbreak can occur. During an epidemic period the disease tends to become more virulent as the infection pressure increases, the result being reflected in the mortality figures, especially among children under the age of 5.

Measles not being generally notifiable, its incidence cannot be gauged with any degree of accuracy, but a reasonable estimate of its prevalence is obtainable through the reports received from head teachers of the London County Council's schools. During the seven months ended June 30th, 1928, 41,417 cases were thus reported, and Dr. Menzies thinks it probable, therefore, that during the epidemic period—measles being a disease especially of pre-school age—a total of approximately 100,000 cases occurred among persons of all ages in London. An interesting observation was that the incidence of the disease fell more heavily on schools in the West and North-Western districts than on those in poorer parts—a phenomenon which may probably be explained by the fact that, in general, children of the poorer classes suffer from measles at a very early age, while those living more sheltered lives do not contract the disease until they have been exposed to infection at school. Of the recorded 1,357 deaths at all ages, 280 occurred among children under 1 year, 575 among those under 2, and no fewer than 1,249 in the age group under 5 years. It is noteworthy, however, that whereas the actual prevalence of measles among school children during the past four quinquenniums has remained more or less stationary, the mortality among them has progressively declined. Although, therefore, there is at present little hope of limiting the incidence of the disease, it is evident that much loss of life may be prevented by energetic and systematic action on the part of the public health authorities. It may be noted that the mortality among patients treated in hospital was 11.9 per cent.; since, however, difficulties were experienced at the height of the epidemic in securing the immediate removal of patients, many of them were no doubt suffering from severe complications, such as broncho-pneumonia, before they could be admitted. The contrast between the mortality of patients in hospital and those at home, in favour of the latter, was very striking in St. Pancras. Dr. Sowden, the medical officer of health, is doubtful whether the whole explanation lies in the fact that the more severe cases were selected for hospital treatment, the basis of selection having been home conditions rather than gravity of illness. In one hospital to which patients from the St. Pancras district were admitted the medical officer stated that the heavy mortality was due to overcrowding of the wards; in view of the special preparations made by the Metropolitan Asylums Board little pressure had been expected, and, owing to building operations, two wards were out of use. We are bound to agree with the authors of the report that the question of hospitalization of measles patients is difficult. It is, on the one hand, always dangerous to remove a child suffering from broncho-pneumonic complications; on the other hand, it is impossible to favour the retention of such a child in an unhygienic environment, in which facilities for the proper care of patients are lacking. The wisest procedure, undoubtedly, is to remove unsuitably housed patients to hospital at the earliest possible moment. Confirmation of this view is afforded in the last report of the Board, in which it is noted that of 8,929 patients admitted to its hospitals during the period October, 1927, to July, 1928, inclusive, 526 (7 per cent.) died. Among 1,528 suffering from complications at the time of admission the deaths numbered 485, corresponding to a rate of 31.7 per cent.; whereas among the 7,401 who were free from complications on admission there were only 141 deaths (1.9 per cent.). The chief cause of death was broncho-pneumonia, which accounted for 542 out of the total of 626.

The present scheme of control adopted by the London County Council aims at securing through the school organization and local public health and voluntary services the earliest possible notification of cases to the medical officer of health; fostering a better recognition among parents of the fact that measles is a dangerous disease; improving the care and nursing of children suffering and convalescing from measles; providing, through district nursing associations, adequate nursing for children treated at home; immediately removing to the hospitals of the Board those infected children for whom proper treatment cannot be provided at home; and transferring children suffering from complications to hospitals where special provision is made for their treatment. From time to time attempts have been made to incorporate the knowledge of the epidemiology of measles gained by the school medical service

[1] Measles. Report of the School Medical Officer on the Measles Epidemic, 1927-28. London County Council, County Hall, S.E.1.

in London into schemes designed to control the spread of the disease. School closure, at one time considered a practical method of prevention, was found to be valueless, inasmuch as it was not resorted to until the outbreak had become well established, and all the susceptibles had already been exposed to infection. A policy of excluding unprotected children from classrooms for prescribed periods on receiving reports of the first cases of measles superseded school closure, but owing to the difficulty of securing sufficiently early knowledge of the first cases it was found to be equally ineffective. For some years past, therefore, the London County Council has concentrated attention upon speeding up the machinery of voluntary school notification. In the recent epidemic, moreover, it adopted the principle of devoting special care to overcrowded and insanitary areas, and, although tangible results were not altogether reflected in the mortality figures—owing probably to a greater virulence of the epidemic in question—Dr. Menzies has no doubt that this method of attack is the right one, and should be pursued and improved. In general, the campaign against measles in London involves the correlation of the powers of the Council as the school authority, and those of the metropolitan boroughs as the public health authorities. The Council undertakes to obtain the earliest possible information of cases of measles, arranging to this end, as soon as a district shows signs of becoming infected, for the school nurse to pay a daily visit to the schools affected. This officer, in co-operation with the teaching staff, at once excludes all suspects, and informs the divisional educational officer of any suspicious absentees. All cases of measles thus disclosed are reported at once to the medical officer of the district where the child lives, and he, in his turn, arranges for the provision of treatment as circumstances dictate.

Since 1918, when Nicolle and Conseil[2] and Richardson and Connor[3] described the use of serum from human convalescents in the prevention and treatment of measles, a number of attempts have been made to manufacture a reliable serum from animals. Notwithstanding, however, the work of Tunnicliff and Hoyne,[4] and of other investigators who claim to have isolated the causal organisms, most observers are agreed that no effective animal serum has yet been obtained. But of the value of serum from human convalescents in the prevention, if not in the treatment, of measles there can now be little doubt; and one turns, therefore, with interest to the section of the London County Council's report in which this method of prevention is discussed. The authors suggest that, measles being essentially a disease of young children, serum cannot be obtained in sufficient quantities, because for various reasons it should never be taken from a young child, much less from one who is convalescing from so serious an illness. It is important to realize, on the other hand, as Sir George Newman points out in his annual report, that older children, at any rate, can usually spare an appreciable quantity of blood without detriment to their health. Obviously the consent of their parents should always be obtained, but this is seldom withheld when it is explained that the blood may be the means of saving a number of lives. Most of the available supplies are at present obtained from adult volunteers, tested for freedom from diseases conveyable to the recipients through the serum; recent work suggests that this source of supply may be much richer than at first appeared, the whole blood of adults with a history of measles, even as far back as twenty-five years previously, having been used effectively in the protection of children who had been exposed to infection.[5] Dr. Menzies suggests as the optimum period for administering the serum the second or third day of incubation, but makes no mention of the view now widely held that, given later, the serum has the advantage of not wholly preventing, but of modifying the attack of measles, thereby securing for the child permanent immunity at comparatively small risk. Convalescent serum, he says, has been used in the treatment of severe cases, but once the disease has become established and shows serious symptoms, even large doses have failed to benefit the patient. The report emphasizes the prophylactic influence of foods rich in vitamin A, both in preventing infectious disease and in protecting those already infected against severe complications—a view which accords in general with that expressed in these columns by Mellanby and Green[6] on the value of vitamin A as an anti-infective agent.

WHAT IS MEDICINE?

THE question What is medicine? though in nature philosophical rather than practical, is not inappropriate for some consideration at the beginning of an academic year, and admits of many answers: *tot homines, tot sententiae*. Is it a means of livelihood and little more than a trade, or is it a form of service to mankind? Is it an art or a science—a kind of engineering of the human body? Is it concerned with man as a whole, or only with his individual organs? Is it parasitic on [illegible]es, or does it offer them its own [illegible]? It is doubtful if the wise man faced with these antitheses will range himself definitely on one side or the other. Medicine, like an umbrella, covers many subjects, and so presents varied alternatives to those who enter on "the physic line," often, perhaps generally, without giving more than a superficial consideration to all the possible reasons for such a momentous decision. Hence it comes about that an accidental or instinctive choice of medicine as the life's work may eventually lead to a congenial career of a kind never dreamt of at the outset; in like manner those who fall in love and endow their future partners with all kinds of properties, some of which may be imaginary, are sometimes compensated by the discovery later of unsuspected virtues. Medicine may appear in very different guises to different individuals, just as in the past its general aspect has seemed to change from time to time; in this it resembles a man who, though continuing to possess the same features, presents them in altered relief and with an expanded setting in correspondence with the experience he gains in the passage of time.

Originally the healing art was closely allied with magic and the priestcraft; it first became independent of religion in the Hippocratic era. A century ago, when Medicine began to be more of a science, Laennec defined the aim of medicine as the cure of

disease. A little later Littré gave an almost prophetic description of medicine as an art having for its objects the preservation of health and the cure of disease, and based on the knowledge of disease or pathology. By the order in which its aims were placed, this anticipated the now accepted view that the ideal of medicine is the prevention of disease, and implied the corollary that therapeutics is a separate branch or appendage of medicine, which is only called into action when the first line of defence—prophylaxis—has been driven in. In a philosophical article entitled "Medicine and science," published rather more than a year ago, Dr. Alfred E. Cohn,[1] of the Hospital of the Rockefeller Institute for Medical Research, classified the activities aroused by an interest in disease as teaching, practice, and research; he pleaded for the recognition of the last of these as a natural science. Cohn regarded the phenomena of disease as part of nature, and thought that their investigation was likely to yield valuable information about the behaviour of living organisms; as indicating the kind of new knowledge which might be anticipated he quoted the late J. G. Adami's *Medical Contributions to the Study of Evolution* (1918). These morbid phenomena were, according to Cohn, distinct from the subject-matter of any other science, and even if classed as bases of physiological derangement they could not be included within the confines of physiology. That this view might well be open to question Dr. Cohn obviously realized when he remarked that the success of physiology has been so great as to "embolden its professors to attempt to extend their labours to the study of disease itself, as witness the institution of departments of research or experimental medicine." At any rate, he would appear to regard the investigation of morbid phenomena, and probably what has been included under "human biology" by Raymond Pearl, as a natural science distinct from others. He would certainly in this connexion divorce treatment (which he described as "an attempt to utilize the knowledge obtained by the study of morbid phenomena for the purpose of interfering with or rectifying abnormal courses") from medicine, for unless this reparation is effected medicine remains as only applied science. This is perhaps a position which many would be quite content to accept.

In a recently published essay entitled "What is medicine?" and dedicated to his two nephews, who are medical students, Dr. E. Rist, physician to the Laennec Hospital, Paris, presents quite another point of view; he illustrates by many examples the wide influence of medicine on human activities, including those of the State, the Law, and various sciences; in fact, he believes that Terence's dictum, *Homo sum; humani nihil a me alienum puto*, applies *more completely* to medicine than to any other profession. Medicine, he shows, includes a knowledge of man in every respect; thus psychology, formerly the preserve of philosophy and investigated almost exclusively by introspection, has now been elucidated by psychopathology and the experimental method. It would appear, then, that medicine is a complex subject. In so far as it comprises empirical knowledge derived from experience, and its practice depends on the application of knowledge obtained from various sciences, it may be regarded as an art or craft; but one branch of it—research—is entitled to recognition as a special science. Medicine thus offers attractions to men of very various minds—humanitarian, "practical," educational, and scientific.

AN AMERICAN STUDY OF B.C.G.

With the forty-fourth annual medical report of the Trudeau Sanatorium, for the year ending September 30th, 1928, is incorporated the twelfth collection of the studies of the Edward L. Trudeau Foundation for research and teaching in tuberculosis—a series of reprints from various scientific journals of papers which have recently emanated from the sanatorium's research and clinical laboratory. Of outstanding interest are the reports by Dr. S. A. Petroff and his research associates of their investigations into the properties of B.C.G. and their interpretation of the contradictory views held by different workers on the virulence of this organism. In the course of their experiments they have been able to demonstrate the production of generalized tuberculosis by direct inoculation of B.C.G.—in one case after the second animal passage—and for these results they cannot accept the explanation of Calmette and his collaborators that positive tuberculosis in animals inoculated with B.C.G. is due to the use of a product contaminated with a virulent tubercle bacillus; it is, they hold, no justifiable criticism to accuse trained workers of such gross carelessness. They have observed that any culture of tubercle bacillus may contain two types of colonies which can be differentiated by their cultural characteristics and virulence for animals. In B.C.G. cultures they have found an "R" colony, which is non-virulent, and an "S" colony, which is virulent, for guinea-pigs. The nomenclature is arbitrary; applied to micro-organisms "R" denotes rough and "S" smooth colonies, but the authors interpret them as "R," meaning resistant to environment, and "S," meaning sensitive. They believe that by continuous subculture on potato-bile media Calmette has gradually eliminated most of the "S" colonies, allowing the "R" to predominate. The virulent "S" colonies, however, have never been completely eliminated, and under favourable conditions they may increase in number to such an extent that reversibility of virulence may occur. The authors go further, and cite experiments which show that even an "R" colony, when inoculated intravenously, may sometimes produce fatal tuberculosis, suggesting as tentative explanations of this phenomenon, first, that there is a possibility that the "R" colony is not completely free from "S" micro-organisms, and, secondly, that mutation of "R" into "S" may take place in the animal body. If the second explanation is valid no one can predict what may happen in the course of time if B.C.G. is implanted in the human body or accidentally carried from human being to human being, or what transformations may occur after such a series of events. Even when B.C.G. confers protection the authors hold that its amount is no greater than that obtained by the use of heat-killed organisms. The cellular reaction observed in animals sensitized with heat-killed tubercle bacilli differing in no way from that seen in animals infected with living virulent organisms, they believe that immunity produced by dead bacilli is also likely in no way to differ from that produced by living bacilli. Moreover, heat-killed organisms used as a vaccine are harmless, for the reason that they do not propagate, while attenuated organisms entering the body may conceivably revert to their former pathogenicity. It is interesting to note that the problems engaging the attention of Dr. Petroff and his colleagues are, as reported by the Chief Medical Officer of the Ministry of Health in his annual report on the state of the public health, at the present time also being investigated under the auspices of the Medical Research Council.[1] Dr. A. Stanley Griffith, working in the service of the Council on the immunizing value of B.C.G., has been unable to confirm the conclusions of Calmette that the ingestion or inoculation of B.C.G. can give complete protection to

[1] *On the State of the Public Health.* Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1928. H.M. Stationery Office. 1929. Price 3s. nrt.

monkeys against an infection with virulent tubercle bacilli. With one exception all the monkeys subjected to B.C.G. vaccination became infected and developed progressive tuberculosis. On the other hand, absolute immunity has apparently been produced in a calf by an intravenous inoculation of B.C.G. Dr. Griffith and Professor J. B. Buxton are conducting experiments to find the relative values of different methods of giving the vaccine, the most effective dosage, and the duration of the resulting immunity.

THE FOOT AND THE SHOE.

EVER since civilized man abandoned the habit of going barefoot or wearing sandals, and first enclosed his feet in boots or shoes, he has had trouble. The stages by which in ancient Egypt the papyrus sandal developed into the papyrus shoe may be traced in the specimens exhibited in the British Museum. When leather superseded papyrus the more rigid material made matters worse, and the old metaphor "where the shoe pinches" is evidence that shoes have "galled the kibes" of our forefathers for many generations. Some of the trouble was inevitable if the foot was to be protected from the weather and injuries from various sources, but much of it has been due to fashion. Not only in Europe, but in Oriental countries, it would appear as though the artificer considered not that the shoe should fit the foot, but that the foot should adapt itself to whatever he and his employers thought the shoe should be. We believe it is strictly accurate to say that till recent years in no case has the form of the shoe truly represented that of the foot within it, sandals excepted. Often it has seemed that the shoemaker has forgotten that a foot looked at alone is not symmetrical, and has made his wares accordingly. The medial pointed shoes and slippers of the Chinese and many other Oriental peoples offer a case in point, but the most glaring example appeared in the fourteenth century in France, when the length of the long pointed shoe—the "poulaine"—was regulated by royal edict, and only those of the highest rank were allowed to wear the most exaggerated recurved shoes with pointed toes, tied or chained up to the wearer's knees. It is true that by a freak of fashion in the sixteenth century for a short time the toes were freed from bondage by the fashion of wearing puffed-out shoes—"snub-nosed" (souliers camus), as Viollet-le-duc called them—with which the portraits of our Henry VIII have made us familiar; but the fashion soon passed, and the smart set returned to its evil ways. There has been a great difference between the fashions of the two sexes in the Western world in this matter of footwear. Perhaps it was natural that among the well-to-do classes, of which the women were expected neither to walk nor to work, purely ornamental considerations should have prevailed. But in these days of sex equality, when woman challenges man to the contest in every field of activity, and when millions of women toil side by side with men, it is surely remarkable that she should choose to emulate her forebears of the days of powder and patches, and try to copy the digitigrade method of progression of the cat and the dog, instead of the plantigrade method of the anthropoids and bears. For this is what it comes to. Dr. J. J. Buka of Pittsburgh, in an article in the *Journal of the American Medical Association* of August 10th, hints at this contrast, and recommends more rational footwear for both sexes, although, probably as a concession to fashion, his "correct" type of woman's shoe is more pointed than is ideal or is considered advisable for the male. In this country it is rare to find men's boots and shoes (in America "boot" is used only for Wellingtons, riding boots, etc.) with a heel higher than one inch, which, assuming the sole to be half an inch thick, gives a lift to the heel of only half an inch—not enough to affect the mechanics of locomotion. The woman's heel is seldom less than two inches high, while the sole is seldom as much as a quarter of an inch thick. Thus the greater part of the weight and stress in locomotion is transferred from the heel to the toes, and the pegtop heel is, as Dr. Buka points out, merely used as "a buffer, a reminder that the heel of the foot must not be walked on, that it should act only as a buttress to steady the forefoot." Nevertheless, many high heels seen in the streets to-day have to bear weight, and not seldom yield under it to one side as soon as they are somewhat worn. Efforts to produce and bring into use suitable shoes are laudable, but the old proverb of the horse and the water comes into our mind; the modern young woman may be shown the reformed shoe, but not be induced to wear it at the sacrifice of smartness (as she thinks it) and of at least an inch of her apparent stature.

THE GENEVA CONVENTION.

THE present position of the League of Nations in respect to dangerous drugs was ably summarized on the final day of the Assembly by M. Fotitch of Czechoslovakia, a member of the Opium Advisory Commission. The Geneva Convention, which came into force in September, 1928, has now been ratified by thirty-one Governments, including twenty-six members of the League. These Governments include those of Great Britain, of all the British dominions, and of India, as well as those of France, Germany, Austria, Spain, Portugal, and Japan. Seven other Governments have announced that steps are being taken towards ratification, and declarations were made at the Assembly by representatives of the Irish Free State, Italy, and Norway of the intention of their Governments to ratify. The view taken at the Assembly was that the immediate ratification and rigid enforcement of the Convention is the most valuable single step that can be taken at present to combat the illicit traffic. Our readers scarcely need to be reminded that the Geneva Convention is the outcome of the conference held in 1924–25 to implement the provisions of Chapter III of the Hague Opium Convention of 1912, which dealt with the control of traffic in medicinal opium and other drugs. M. Fotitch declared that the discussions which have taken place during the recent Assembly have shown an unusual sense of the seriousness of the position, and a general determination to put an end to the illicit traffic as soon as possible. As will be seen from the note by Dr. Hilda Clark printed at page 673 this week, the debates have been largely occupied with the question of limitation of manufacture. For the first time in the history of the League there has been brought about an agreement among the manufacturing countries as to the desirability of such limitation, to be secured by means of an international conference which would determine the total amount of narcotic drugs required to meet the legitimate medical and scientific needs of the world, as well as the quota to be allocated amongst the various manufacturing countries. A resolution was proposed by the British delegation asking the Council of the League to invite the Governments of the countries in which morphine, heroin, or cocaine are manufactured to confer together as to the possibility of arriving at an agreement on these points, and this resolution was adopted with the extension that the proposed conference should also include representatives of the chief "consuming" countries. Meanwhile the Secretariat of the League has been instructed to take certain steps which are likely to put the opium work of the League upon a sounder footing. It has been requested to study and prepare a report on the data in its possession regarding the legitimate consumption of dangerous drugs; also to consider the possibility of preparing a list of all the laws now in operation in the various countries regarding drug traffic, with a view

to facilitating the more effective operation of the Geneva and Hague Conventions, and, further, to make a careful comparative study of all the seizure reports with a view to bringing out the chief administrative weaknesses revealed. There was evident at Geneva a feeling that up to now the work of the League in this field had been stultified and its authority flouted; but as a result of the debates, and particularly of the acceptance by the manufacturing countries of the principle of direct limitation of manufacture by means of international agreement, a much more optimistic feeling prevailed at the close.

THE IDEAL MEDICAL MUSEUM.

DR. S. H. DAUKES is one of those fortunate men who have lived to realize a great ambition, made possible by the munificence of Dr. Henry S. Wellcome. As a student Dr. Daukes was impressed with the dullness and deficiencies of most museums attached to medical schools, and conceived a scheme for their regeneration. He had to wait for his opportunity; it came to him first in 1917–18, when he was placed in charge of the Army School of Hygiene at Leeds. He resolved to teach his men objectively; trenches were cut, dug-outs made, latrines erected, incinerators set up, and kitchens built: these became his school of army sanitation. The success of the school was noted by Dr. Andrew Balfour, who perceived that the officer in charge was a born teacher, one who was brimming over with fresh ideas of a kind which could be put into practice. Dr. Balfour invited Dr. Daukes to become curator of the Wellcome Museum of Tropical Medicine. So successful was the new curator in giving a graphic exposition of tropical diseases that he was permitted to extend its scope to embrace all forms of illness to which human flesh is heir. In this way there has come into being at Endsleigh Court, W.C., a unique medical institution of which London may well be proud. In the ordinary medical museums, specimens stand in monotonous rows detached from the field of clinical utility. In Dr. Daukes's system the patient and his disease take the centre of the picture; by aid of photographs, drawings, charts, and models the manifestations and symptoms of the disease are given a graphic representation. Special means of diagnosis are depicted where necessary. On one side of the patient are set out the environment or conditions predisposing or causing the disease; if the causative organism is known its life-history is depicted and its mode of conveyance exemplified. On the other side of the patient are set out specimens to illustrate the nature of the lesion—the organs attacked and their pathological changes. The visitor has also set before him the nature of the changes in these organs as revealed by the highest powers of the microscope. Thereafter follows an illustrated epitome of treatment, including preparations of drugs. The picture ends by a series of illustrations to bring home to the student the most effective means of prevention. The aim is to tell the complete story of every disease by an appeal to the eye. In the traditional medical museum the student is supplied with the material, but he himself must supply the imagination which restores dead specimens to the bodies of living patients. In the new scheme Dr. Daukes supplies the imagination; the student has only to open his eyes and permit the stories which Dr. Daukes has told with great ingenuity and often with the happiest effect to sink home. Under this new conception the museum, in place of being merely the appanage of the post-mortem and dissecting rooms, becomes the integrating centre of education in a medical school—the centre where all departments of knowledge are focused on the central problem of the patient and his disease. Dr. Daukes[1] has written a book in which he gives an account of the history of the museum under his charge, the aims he has sought to realize and the methods he has found most helpful. It is a book which will make its chief appeal to curators of museums, but the Wellcome Museum itself, once its merits become known, will appeal to medical men, to medical students, and to the layman. From the point of view of medical propaganda modern medicine could not be better served than by the Wellcome Museum of Medical Science.

THE HOUSING PROBLEM.

AMONG the hopes which spring eternal in the human breast is that of the abolition of slums. Unfortunately, the problem is beset with many difficulties, and the results of the best laid, and most expensive, schemes are often unexpected. Since the war vast sums have been spent on housing; but, as Dr. J. Howard Jones, medical officer of health for Newport, points out in a pamphlet, *The Housing Problem*, reprinted from the yearbook of the Welsh Housing and Development Association, very many of the new buildings have been occupied by the artisan-clerk type of tenant, the housing of whom since the war has rather distracted attention from the problem of helping the small wage earner. Work on old courts, cellar dwellings, and dilapidated cottage property has been suspended, so that the conditions under which a large proportion of these small wage earners live are worse than before the war. In Cardiff the percentage of houses occupied by more than one family has increased in the last two years. According to Dr. Howard Jones the morals of the slum dweller have deteriorated; he no longer regards the payment of rent as a primary duty, and this is attributed to the Rent Restrictions Act. Landlords complain that money which was formerly ear-marked for rent is now spent on amusements, it being known that landlords cannot get rid of unsatisfactory tenants. Dr. Jones quotes Mr. E. D. Simon as maintaining that clearance of slums and dilapidated houses can only be accomplished by intensive house building; but he notes also that a large number of the houses built in 1919–21 are still costing central and local authorities over £1 each per week more than is received as rent. The one ray of hope in Dr. Jones's pessimistic pamphlet is the suggestion of a return to the pre-war method in Newport of dealing with dilapidated cottage properties. It was the habit of the Newport corporation to address comparatively polite letters to the owners and occupiers of insanitary premises. The owner was offered the advice and assistance of an inspector, and if he carried out the required improvements the inspector paid a quarterly visit to the tenant to see that he kept the premises clean and in a sanitary condition. In this way the tenant was educated in his duties and responsibilities; the system benefited the landlord; and the corporation was spared the expense, unpleasantness, and delay attending recourse to legal proceedings under the Housing and Town Planning Act. Apparently, however, the gleam of hope contained in the suggestion of a return to this system is clouded by the existence of the Rent Restrictions Act.

THE Bradshaw Lecture on "The virulence of the micro-organism of infective disease" will be delivered before the Royal College of Physicians of London by Dr. J. A. Arkwright on November 5th. Dr. G. F. Still will deliver the FitzPatrick Lectures on "The history of paediatrics in the seventeenth and eighteenth centuries" on November 7th and 12th. The Lloyd Roberts Lecture, entitled "An Oxford Movement," will be given by the Right. Hon. H. A. L. Fisher on November 14th. The lectures will be delivered at the College, Pall Mall East, S.W.1, at 5 p.m.

Opening of the Winter Session.

CHARING CROSS HOSPITAL.

DISTRIBUTION OF PRIZES.

A large gathering of old students, attracted by a special post-graduate course that was given by the staff throughout the week-end, was present on October 5th at the opening of the winter session and distribution of prizes to students of Charing Cross Hospital Medical School. Dr. David Forsyth, in the course of his inaugural address, said that a vacated convent on Haverstock Hill had been bought for the purpose of housing the nurses and other hospital staff, and the accommodation thus set free at the hospital would be available for use as wards for paying patients. The convent had cost £10,000, and an additional expenditure of £3,000 would be necessary to equip it to house some 300 people. Of the £100,000 required for the extension of the hospital £98,000 had been raised. Extensive alterations were being carried out in the casualty department, where, owing to the situation of the hospital, many victims of traffic accidents had to be treated. Those who remembered the financial difficulties of the hospital before Mr. George Verity became its chairman would feel the deepest gratitude for the state of affairs he had brought about; during the past few years he had raised £250,000 on behalf of the hospital. Mr. J. Bright Banister, acting dean of the Medical School, said that, owing to the drastic change which had been made in its constitution, the Medical School had two or three difficult years before it, but there was every reason to hope that it would then once more assume its rightful place among the great medical schools of London. The prizes were presented by Lady Rees.

The Annual Dinner.

The annual dinner of past and present students was held the same evening at Gatti's Restaurant, with Dr. J. M. H. MacLeod in the chair. In proposing the toast of "The Hospital and Medical School" Mr. N. C. Lake said that though, in what was essentially a Charing Cross Hospital family party, this was always a popular toast, there were, on the present occasion, special reasons for its enthusiastic reception. The opening of the session coincided with the completion of the most considerable addition that had been made to the hospital in the last quarter of a century. The premises of the Westminster Ophthalmic Hospital had been adapted to house a number of special departments, and it was hoped that soon the present congestion of the wards would be relieved. An added reason for enthusiasm, said Mr. Lake, was the fact that the dinner was attended by the most representative body of old students that had come together for many years. Some of those present had probably not been in the hospital since their graduation, but had now returned, like prodigal sons, to partake of the fatted calf in the form of a post-graduate course. He did not wish to press the parable too far and suggest that they had wasted their substance in riotous living, or, in view of the fact that some had honoured guests with them, that they ended up by becoming feeders of swine. To some old students, revisiting the hospital after a long absence, the wards must have appeared shrunken in size, the present generation of students not so fine as in their own days, and the staff less efficient. He assured them that those who were working and teaching in the hospital perceived no such deterioration; the phrase "there were giants in those days" represented, indeed, subjective change rather than historical truth. Charing Cross men were often critical of their hospital and school; he was critical himself, but he had every sympathy with the Irishman who was abusing his own village and then punched the head of the first stranger who ventured to agree with him. Mr. Banister having made sympathetic references to the illness of the dean, Dr. F. H. Young, of whose progress towards recovery he was able to give an encouraging report, stated that the school was on the threshold of a difficult phase of its career, and for the next two or three years nothing very startling was to be expected of it. The number of entrants was, however, increasing, and soon the facilities afforded by the hospital and its efficient staff would be used to the full by as large a body of students as the school could accommodate. He asked all old students to subscribe to the *Charing Cross Hospital Gazette*, so that they might learn what was happening in the hospital and maintain touch with its activities. Dr. W. C. Bosanquet, in proposing "The Health of the Chairman," referred to him as one of those who, after a brilliant career in a Scottish university, had unselfishly decided to confer the advantage of his presence and attainments upon the southern part of the island. He remembered how, many years ago, in the dermatological department, they had both sat at the feet of James Galloway and learned the names of mysterious skin lesions coupled with the equally mysterious names of gentlemen from Central European universities, and, at the same time, heard of what was called a rival institution—St. John's Hospital for Diseases of the Skin. Much had changed since then; in Central European dermatological schools students often heard the name of MacLeod, and Dr. MacLeod, far from carrying on the tradition of rivalry between St. John's Hospital and the skin department at Charing Cross, had become a senior and honoured member of the staffs of both. In his reply Dr. MacLeod referred to the distinguished group of physicians—Green, Mitchell Bruce, and Frederick Mott—who were associated with Charing Cross when he first joined the hospital; at that time also on the staff of the hospital was James Mackenzie Davidson, the first man ever to treat a malignant growth with radium in this country. Dr. MacLeod gave an amusing account of the trouble he was put to in preventing an enterprising pressman from giving publicity to his name and that of Dr. Davidson in connexion with the successful treatment of rodent ulcer by means of radium. In conclusion, he referred to the Local Government Act and its possible repercussions on the voluntary hospitals. Whatever happened, he was certain that Charing Cross would continue to do its work of caring for the sick and advancing medical knowledge in the future as it had done in the past.

ST. MARY'S HOSPITAL.

OLD STUDENTS' DINNER.

Sir John Broadbent, Bt., presided over the annual dinner of the past and present students of St. Mary's Hospital School, which was held on October 4th. The toast of "St. Mary's Hospital and Medical School" was proposed by Lieut.-Colonel H. E. Verey, chairman of the hospital board. After commenting briefly on the importance of a medical school to a great hospital Colonel Verey referred appreciatively to the valuable donations received from Lord Beaverbrook and the late Lord Revelstoke for the building of the new Medical School, and to the gift of £20,000 by Lord Iveagh towards the rebuilding of Sir Almroth Wright's department. It would thus be possible to make a start with the erecting of the school building on the island site early next year. Work on the new laboratories would similarly begin shortly, and, later on, a much larger nurses' home would be provided. Accommodation would thus become available for beds for paying patients, which Colonel Verey considered to be one of the most urgent needs of St. Mary's Hospital. A warm tribute was paid by the speaker to Mr. Warren Low, who was soon to retire after having been a tower of strength to the hospital; regret was expressed at the resignation of Mr. Leslie Paton also, and mention was made of the deep

sense of loss occasioned by the untimely death of Mr. Kenneth Lees. Dr. C. M. Wilson, dean of the Medical School, replied to the toast, and sketched an interesting picture of the great change which had come over the prospects of the school in the last ten years. In 1919, he said, the financial position was extremely gloomy, and the continued existence of the school was gravely threatened. The desperate struggle for life which had ensued had been the chief factor in its phenomenal progress; thus, such an activity as good post-graduate training was anticipated by St. Mary's Hospital before other London hospitals had realized its value. Some indication of what had been done was shown by the fact that although the expenses of the Medical School were now four times that of the corresponding cost in 1913, when there was a bank overdraft, the school was now paying its way. For the new buildings a sum of about £150,000 was available, and it would be possible to arrange for the provision of a good gymnasium and swimming bath. In fact, St. Mary's was out to establish the best possible school for medical students, both as regards their earlier training and their later progress. An ample supply of house appointments existed, and it was significant that new entries were being received from all parts of the Empire.

Mr. G. P. Harben, a member of the board of St. Mary's Hospital, proposed the toast of "The Chairman," and eulogized the valuable work which Sir John Broadbent had done in the last quarter of a century. He recalled the fact that his own father had been closely associated in working for the hospital with Sir William Broadbent; great difficulties had been overcome, and useful progress made. Since the coming four years would be a far from easy time Mr. Harben expressed the strong hope that Sir John's assistance would be available for St. Mary's in spite of his resignation. The toast was drunk with great enthusiasm. The Chairman, in his reply, gave details of the improvements which his own father had been able to effect in conjunction with Mr. Harben's father, as regards the hospital and the Medical School. He referred to the advent of Sir Almroth Wright, and the beginning of his work in very humble quarters, which contrasted sharply with the fine prospect now, a prospect which was largely due to the great efforts made by Dr. Freeman and the staff of the pathological laboratory to win assistance for the work of enlargement. A little later the Chairman rose again to call attention to the presence of the Inter-Hospital Cricket Challenge Cup, and to propose the health of the team, which was drunk with enthusiasm; the captain, Mr. Maitland, replied briefly, and mentioned that the cup had not been won by St. Mary's since 1899. The formal proceedings ended early, and the time set free for social intercourse enabled old friendships to be strengthened and new ones formed.

ST. THOMAS'S HOSPITAL.

OLD STUDENTS' DINNER.

The new winter session at St. Thomas's Hospital opened without formal ceremony, but a reunion meeting was held on October 4th at St. Thomas's House on the occasion of the annual old students' dinner. The chairman, Dr. H. G. Turney, consulting physician to the hospital, was supported by the President of the Royal College of Physicians; the medical heads of the Navy, the Army, and the Royal Air Force (Surgeon Vice-Admiral Arthur Gaskell, Lieut.-General H. B. Faweus, and Air Vice-Marshal David Munro); the treasurer and almoners of the hospital, and the dean of the Medical School; Sir George Makins, Sir Cuthbert Wallace, and Sir Farquhar Buzzard, of the consulting staff; Professor G. E. Gask, representing the University of London, and the headmaster of Merchant Taylors' School. In proposing the toast of "Prosperity to St. Thomas's Hospital and Medical School," the Chairman touched lightly on the theme of "Doctors who are not doctors," and on the history of the hospital from the thirteenth century to the present time. The Treasurer (Sir Arthur Stanley), in response, said that they were entering on a year of extreme importance for St. Thomas's; the acquisition of a site on the opposite side of Lambeth Palace Road had brought with it the problem of where to put the out-patient department. It was a mystery to him how the work of that department was carried on in its present quarters; since 1914 the attendances had grown from 249,000 to more than 600,000. The suggestion had been made that the existing Medical School building should be taken over and the out-patient department rebuilt on that site, the Medical School being transferred across the road. This would cost a very large sum, perhaps half a million, but they had a very strong case for launching an appeal for this purpose. Professor L. S. Dudgeon (dean of the Medical School), who also responded to the toast, said that over £200,000 would be needed for the new Medical School, and until that had been obtained the out-patient department could not be rebuilt. He then referred to some of the losses of the past year, in particular to the deaths of Sir Seymour Sharkey, a great teacher of clinical medicine; Sir Hector Mackenzie, a physician popular with all alike; and Dr. F. F. Caiger, who was made emeritus physician to mark his outstanding position in the study of infectious fevers. They were losing by retirement Professor F. G. Parsons, who had taught anatomy to generations of St. Thomas's men, and Dr. J. S. Fairbairn, whose enthusiasm, originality, and organizing power would be greatly missed. "The Health of the Guests" was proposed in happy terms by Sir Percy Sargent, senior surgeon to the hospital, and responded to by Sir John Rose Bradford, P.R.C.P., who recalled agreeable personal associations with St. Thomas's. The last toast, that of "The Chairman," was proposed by Dr. A. E. Russell, senior physician, who spoke of Dr. Turney's unbroken work for St. Thomas's since his nominal retirement from the staff ten years ago, and of his own debt to his old teacher and friend. The Chairman then, after a brief acknowledgement, handed, on behalf of past and present students, a cheque for £300 and an illuminated address to Robert S. Hopkins, the school bedell, to mark the beginning of his fiftieth year of service in the Medical School. Mr. Hopkins's long and faithful service, combined with that of his late father and grandfather, has covered a period of over a hundred years.

KING'S COLLEGE HOSPITAL.

ADDRESS BY Sir GREGORY FOSTER.

The centenary session of King's College Hospital Medical School was opened on October 2nd, under the presidency of Lord Gorell, chairman of the committee of management of the hospital. Dr. H. Willoughby Lyle, the dean, stated in his report that the total number of students was 295. A centenary appeal for funds for the extension of the school buildings and the provision of further facilities for investigation and research was projected, the sum aimed at being £30,000.

Sir Gregory Foster, Vice-Chancellor of the University of London, addressed the company on certain tendencies in professional education. He gave it as his opinion that in early school life too many subjects were attempted, while towards its end there was apt to be premature specialization. Not many years ago the average medical student commenced his medical studies equipped only with a general, and usually a mainly literary, knowledge. To-day the vast majority of medical students came up after having had a considerable training in chemistry and physics and some instruction in biology. The tendency of education, whether during the school or the university period, was towards specialization, and this involved some loss in that the wide humanitarian training which was once the hallmark of all the great schools of this country, and had so vividly influenced the country's life, was to a large extent gone. One of the great problems of the educator was to recover what had been lost. It was not merely that the classical languages had ceased to hold their former place for those who entered the learned professions, but that owing to the multiplicity of subjects which had to be taken the humanitarian training given in former days by the classics had disappeared. Efforts, not yet fully successful, had

been made by the schools to substitute for the classical discipline a discipline based upon a fuller knowledge of our own and other languages and literatures, especially French and German.

After pointing out that the perplexities and difficulties of university training arising from the growth of knowledge and consequent specialization were apparent in every one of the faculties, Sir Gregory Foster, speaking as a layman, proceeded to consider how this state of affairs had affected the general practitioner, who, he said, no longer had the place he used to occupy in the life of the people. Such were the ramifications of medical practice that the general practitioner was being driven more and more to resort to the specialist. Patients were sent by the general practitioner to the specialist, and then on perhaps from one specialist to another. Under these conditions the application of the doctrine that it was the patient, not the disease, which should be treated became more and more difficult. The remedy was to associate more closely, somehow, the general practitioner with the public medical service and the hospitals. The linking-up into the general system of the public health service of what had hitherto been known as Poor Law infirmaries seemed to provide opportunities for the general practitioner to keep himself up to date and to re-establish himself in the life of the community. The voluntary hospitals, especially those with medical schools, must join in this great co-operative movement; if they did so there would be no question about the survival of the voluntary system. Whatever might be the chosen remedy for the difficulties he had mentioned, he thought that, while the teaching and training of the undergraduate should throughout be informed by the research method, it must, somehow or other, if it was to have life and balance and proportion, be made more emphatically a well-ordered whole. In speaking of the research method he meant that the undergraduate must be trained throughout to know the sources of knowledge, and to read, as far as possible, original papers rather than a multiplicity of textbooks.

In conclusion, Sir Gregory Foster gave some particulars about the University of London. On its teaching and research side the University included thirty-eight schools; there were twelve general medical schools, nine other schools for the teaching of special branches of medicine, and five for the promotion of research in various medical fields. He claimed that this was a provision for medical education without parallel in any other university in the world.

ROYAL DENTAL HOSPITAL.

ADDRESS BY DR. WILLIAM HUNTER.

At the opening of the winter session of the Royal Dental Hospital of London on October 2nd, Dr. WILLIAM HUNTER, consulting physician to Charing Cross Hospital, gave an address on the progress and increasing importance of the work of the dental profession in relation alike to personal and national health.

In recent years, said Dr. Hunter, there had been a growing recognition of the fact that the teeth were the seat of an infection which was more significant than any other in causing and complicating medical and surgical diseases in all parts of the body. From being the humble handmaiden of her two older sisters in the healing art—medicine and surgery—dental science had become a veritable Cinderella, and her work was regarded as one of the most important in the realm of preventive medicine. This revolutionary change of outlook had been initiated some thirty years ago by the investigations and writings of the speaker, who had shown that oral sepsis was the cause of many diseases whose connexion with dental infection had previously not been suspected. Primarily it was the medical profession which was specially concerned with the new problems created by these investigations, and it was upon the doctor that the first responsibility lay for recognizing the existence and significance of oral sepsis in his patients. Dr. Hunter deprecated a tendency to shift the responsibility to the dental profession, the problems, in his view, concerning not simply the teeth, but a great infection so widespread in its effects that it was now recognized to play even a greater part in medical than in surgical diseases. Oral sepsis was often the source of other septic infections with which the surgeon had to deal—for example, in the tonsils, glands, throat, nose, pleura, and gastro-intestinal tract. The speaker quoted Lord Moynihan's view of the dependence on focal sepsis of anaemia, glandular diseases, certain obscure fevers, rheumatic infections, infections of the kidney, many affections of the nervous system, and perhaps all forms of cardiac disease, and added that during the past twenty years similar recognition had been given to the part played by dental sepsis in the causation of many forms of eye diseases, diseases of the skin, and thyroid and pancreatic diseases, including diabetes.

The dental surgeon, continued Dr. Hunter, had for some time past added radiography, local anaesthesia, and bacteriology to his other equipment. Radiography had revealed the extent and variety of the septic conditions in and around the teeth and their sockets, and had further helped the dental surgeon by enabling him to show the patient the actual conditions present, and thus convince him of the need for the prescribed treatment. Moreover, the dental surgeon now had the helpful co-operation of the doctor, who was able to correlate the patient's medical complaints with the dental infection, and both the dental surgeon and the doctor often had occasion to see the striking improvement of health which followed the removal of such infection. The lecturer then proceeded to consider the prevention of oral sepsis, and suggested that the problem could be met only by work among children of school age, who could all be brought under observation and inculcated with proper habits of mouth hygiene. The chief measure required was the provision in the schools of dental nurses, who would personally impart instruction in mouth cleanliness and stimulate the interest of the children themselves. He had himself seen the efficacy of simple measures of antisepsis in investigations he had conducted between the years 1904 and 1907 in the course of his work as physician to the London Fever Hospital. A study was made of 648 patients, mostly children of school age, 43 per cent. of whom had some degree of oral sepsis. As a result of using simple measures of oral antisepsis the incidence of secondary adenitis fell from 9.6 per cent. in 1904 to 1.8 per cent. in 1907; cellulitis of the neck from 5.2 per cent. to *nil*; and glandular suppuration from 1.7 per cent. to *nil*. Even more interesting was a later sequel of this work: when he returned to the Fever Hospital after the war he found that from being present in a quarter to a half of his patients, oral sepsis had practically disappeared. It was clear that this gratifying change was due to the increased dental care that had been provided for the school children of London. In 1906 the London County Council started a dental service in a single school of 245 children; in 1927 the service had so expanded that dental treatment was given to 125,000 children. The number of dental surgeons employed by the council had increased from one to eighty-six, and sixty-one dental centres, covering practically the whole County of London, had been established. The improvement was reflected in a marked diminution in the average number of carious teeth per child, and the drop in the incidence of cervical adenitis, sore throat, anaemia, and maldevelopment. With such a body of evidence before it, concluded the lecturer, not only the dental and medical professions, but the general public, would learn to realize as it had never done before the tremendous effects of oral and dental infection both on the health of the individual and on that of the nation.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.

ADDRESS BY DR. H. H. RUSBY OF COLUMBIA UNIVERSITY.

At the opening of the eighty-eighth session of the School of Pharmacy of the Pharmaceutical Society of Great Britain on October 2nd the address was given by Professor HENRY H. RUSBY, M.D., who has been professor of botany, physiology, and materia medica at Columbia University, U.S.A., since 1888; he was presented with the

Hanbury gold medal for the promotion and prosecution of original research in chemistry and natural history.

Taking for his subject "The authentication of materials used in research," Professor Rusby gave numerous illustrations of the ignorance which still existed as to the identity of the drugs now in use, and the possibility of materials taken from commercial sources not being genuine, and being therefore unreliable for research purposes. He said that the corner-stone of official and legal standardization of vegetable drugs was the statement of their botanical origin. Owing to the absence of identification of this kind, such vague definitions as the following were found in the *Pharmacopoeia*: Asafoetida, "derived from *Ferula asafoetida, Ferula fetida*, and other species of *Ferula*," and, again: Siam benzoin, collected from the same species as Sumatra benzoin, "or from other species of Styrax." Authentication had been carried to perfection in the basic sciences. In his own special field of botany it was declared that no name assigned to any species should be held valid unless it was supported by a description sufficient for identification, but even that was found to be insufficient in the case of most descriptions previously to recent times, when nearly all descriptions were framed merely so as to distinguish the species described from all others then known; as additional species were published, these early descriptions had been found quite inadequate for purposes of identification. In such circumstances all that had saved botanical nomenclature, extending back for centuries, was the custom which had always prevailed of preserving the original specimen from which the description was drawn, and known as the "*type*," in suitable herbaria, where a comparison could always be made in doubtful cases. Professor Rusby here added that it was because in Great Britain such remarkable care had been taken and so large a sum of money expended in building up these collections of type specimens, that no botanist in any part of the world, engaged in extensive critical work, could long continue successfully without visiting England for comparative study. He added that it would not be going too far to decree that no report of research work in pharmacognosy—the branch of pharmacology relating to unprepared medicines—chemistry, pharmacodynamics, or therapeutics should be regarded as valid or given serious recognition unless such report stated where authenticated samples of the material employed had been permanently deposited. The earlier in the history of the drug that this could be done the better, but it was never too late, as witness Farwell's recent tracing of *Cascara amarga* to the genus Sweetia in the family Papilionaceae, whereas no student of materia medica ever expected it to be referred to any other family than the Simarubaceae. It was a fact worthy of note that Farwell had taken pains to preserve specimens of the bark and of the tree yielding it, in order that all doubts for the future might be eliminated.

In concluding his address, Professor Rusby impressed upon his hearers the fact that every good student was a discoverer at every step taken in his career. That method of instruction which led the student to investigate and discover his facts and principles for himself was the one that produced the best scholars. It was as obligatory on the students while working in the School of Pharmacy to observe all the rules for authentication and verification as it was for the most eminent of discoverers, and it was this habit, formed while those discoverers were students, that contributed more to their success than did the immediate conditions connected with their discovery. Still more important would these habits be to them as practical pharmacists. No longer could chemists deal wholly with chemistry, or botanists with botany. Every worker in a special field was obliged to know enough of other fields to enable him to keep his bearings and to interpret correctly the relations of all facts that came before him. When a student found himself disposed to dodge a lesson in physics because of his love for histological examination, or to neglect his bacteriological preparations for chemical experimentation, he should try to remember that it would be impossible successfully to carry his work very far in one direction without being required to observe and determine correctly in each of the others.

MOTOR CARS FOR 1930.

THE OLYMPIA SHOW.

[From our Motoring Correspondent.]

To many persons the possession of a motor car is a luxury: to members of the medical profession, faced with the need of completing the daily round as quickly as possible, or even of extending their area of practice, it is a necessity: the annual Motor Show is therefore an event to which they look forward keenly, for it enables them to obtain easily a comprehensive picture of the progress that has been made by the different manufacturers and of the general trend in the design and construction of motor vehicles. This year's exhibition, the twenty-third organized by the Society of Motor Manufacturers and Traders, will open at Olympia, London, W., on Thursday next, October 17th, and continue daily from 10 a.m. to 10 p.m. until Saturday, October 26th. The charge for admission on the opening day is 10s., on Fridays and Saturdays 2s. 6d., and on all other days 5s.

Despite the fact that there are only eighty-six stands in the car section, as against ninety-eight a year ago, the show maintains its international character, the products of no fewer than nine countries being on view, those of Britain, France, and America predominating. British cars are the most numerous, but there are more foreign than British makers represented, thus emphasizing the importance which Continental and American manufacturers attach to the market in Great Britain. Notwithstanding the keen foreign competition and some uncertainty with regard to the future of the McKenna import duties, there would seem to be renewed vitality in the activities of British manufacturers, and there is every reason to believe that the British vehicles of 1930 will be able to hold their own with those of any country.

Mechanical Changes.

Except for improvements in detail and a distinct trend in favour of cars with six- and eight-cylinder engines, the 1930 cars do not show any startling change from those of the past year, what alterations there are being in the direction of a smarter external appearance by the adoption of neater radiator and body designs and harmoniously blending tones for the paintwork. Makers are also competing with each other in catering for the comfort of both the driver and the passengers by including many little conveniences which were formerly regarded as luxuries and accordingly charged as extras.

Although, nowadays, the majority of motor owners are inclined to take the efficiency and reliability of cars for granted, there is still a large section interested in the progress of engine design and in other mechanical details, and for them it may be useful to study briefly a modern chassis. So far as engines are concerned, apart from the trend towards six and eight cylinders, there is, except perhaps for a slight reversion from overhead to side valves, no striking new departure. Carburettors are being more generally provided with air cleaners, and lubricating systems with oil purifiers and coolers, while, to the regret of some older motorists, coil ignition, drawing its current from the lighting and starting battery, is steadily gaining on the magneto. One detail improvement, in the more expensive cars at least, is the fitting of shutters to the front of the radiators, thermostatically opened and closed with the object of maintaining the temperature of the cooling water at a point which ensures maximum engine efficiency.

The alteration in radiator outlines is probably one of the most noticeable changes. Morris led the way in this direction some three years ago when he discarded the old round-nosed type. Other makers have held on until this year to their long-used patterns, but among those who have adopted new and more attractive forms are Messrs. Humber, Hillman, and Swift. Even the Renault Company, whose cars have long been noted for a radiator at the dashboard end of the engine bonnet, have at last come into line with the prevailing practice of placing radiators

at the front, though their design still differs materially from that generally adopted.

Sleeve-valve engines, while retained by the firms who have used them for years, have found no new adherents, the main departure being a "straight-eight" sleeve valve adopted by a Belgian company. Another novel eight-cylinder is the Lancia from Italy, whose cylinders, instead of being in line or arranged in V-form, are grouped side by side in two sets of four. The Daimler "double six" is the only British twelve-cylinder vehicle. At the Salon at present in progress in Paris the Voisin Company are attracting attention to a new chassis fitted with a V-type twelve-cylinder sleeve-valve engine, the first of the kind. At the time of writing, however, it is not known whether the car will be on view at Olympia. The Jowett continues to be the only exponent of the two-cylinder engine, the Trojan Company of the two-stroke motor—which is now, in the pleasure car, of the vertical instead of the horizontal type—while the American Franklin car is still alone in using air-cooled engines.

Quieter Change-speed Gears.

Unit construction of engines and gearbox is still the order of the day, and clutches of the plate type, either running dry or working in oil, are the most popular. Three-speed gears are mainly used on the smaller cars, but on large cars four speeds are *de rigueur*, a trend which even American makers are now following. It is noteworthy that, in spite of the tendencies towards six- and eight-cylinder engines and the claims made for them in the direction of increased flexibility, four-speed gearboxes should be fitted. Except in very hilly districts the bulk of the running is to-day done on the top speed, the first gear being only required to set the car in motion, and although it is admitted that gearboxes are provided with the object of preventing any overstraining of the engine, thereby extending its useful life, motorists nowadays are inclined to look askance at cars which require frequent use of the change-speed lever. As for gearbox control, the centrally disposed lever appears to be the most popular, and in some cases the levers are being made of a length that makes for more convenient operation than hitherto.

Except that Armstrong-Siddeley's retain the mechanically controlled or "self-changing" gearbox introduced last year as an optional fitting on two of their models, and that several four-speed gearboxes in which "third" is claimed to be as quiet as "fourth" are now to be seen, there are no new departures of note in this part of the car's anatomy, nor does the "free-wheel" device about which much was heard a year ago appear to have made any noticeable headway.

Motor engineers still show individual preference for metal or fabric universal joints, while for the final drive, although worm-gearing is still used by some manufacturers, spiral-bevel-gearing is found on the majority of cars. Brakes on all four wheels are now universally employed, those operated by the foot being usually assisted nowadays by compressed air or hydraulic servo mechanism. Brake efficiency has also been improved by the employment of larger drums and better friction lining material. Chassis suspension continues to receive attention. Although independent wheel suspension has not progressed as far in this country as in France, there would seem to be a reversion from the cantilever to the semi-elliptic spring, while shock absorbers of one form or another are universally fitted. One notes, too, that oilless spring shackle bolts are now being much more widely adopted. In road wheels popularity lies between the steel spoked and wire types, with a growing use of the latter, despite the fact that, from the owner-driver's point of view, they are not so easily cleaned. Tyre manufacturers, although now providing us with tyres having treble the life of those of pre-war days, are still striving for even better results.

The Dazzling Headlight Problem.

Those who have to do much driving at night will naturally desire to know what progress is being made in connexion with the difficulty of dazzling headlights. Early in the year the Royal Automobile Club held a demonstration of anti-dazzle devices, but although many ingenious arrangements were displayed it would seem that the difficulty has not yet been entirely overcome. The demonstration showed, however, that a good deal of thought is being centred on the problem, and doubtless some simple, yet effective, method will eventually be discovered. In the meantime, many forms of dipping headlights, lamps with dipping reflectors, and others with full- and dim-light bulbs, as well as several anti-glare devices, have been put on the market, and are being supplied as part of the equipment of many new cars. Lighting and starting equipment is also continually being scrutinized for improvement, this being particularly noticeable as regards the batteries. Instrument boards, too, are being more neatly arranged, and in some cases are less complicated in that certain controls have been removed to the steering wheel.

Both for windscreens and the windows of covered cars unsplinterable glass—of which there is now quite a variety on the market—is being employed on many cars without extra charge, whereas a year ago it was only obtainable as an extra. Pneumatic upholstery, too, is being more widely adopted, while bumpers, although their use has not yet become general, are more frequently seen and are of a neater design than those first introduced. Another device which is making slow progress in England, although quite generally used on Continental cars, is the direction indicator.

Each motor manufacturing concern has its own ideas on the trend of the motor movement, and these are so varied that it is difficult to generalize. It is certain that there are more car models with six- and eight-cylinder engines and fewer with four cylinders, yet the show reveals many paradoxes. Thus there are firms that have dropped "fours" to concentrate on "sixes," others that are confining their output to "fours," still others producing "fours" and "eights," others "fours," "sixes," and "eights," while one German firm is limiting its output to only the eight-cylinder chassis, and one model at that. The Alvis continues as the only British example of the front-drive car, although there are several in France, and one or two new ones in America.

Cars for Owner-Drivers.

The show, as usual, maintains its wide appeal, for while there is again a large selection of luxurious cars for the wealthier classes who are in a position to employ expert mechanic-drivers, the note of the exhibition is the increasing attention that is being paid to the requirements of those who not only drive, but also look after their own cars. The past year has witnessed a further marked development in the car servicing and "valeting" facilities provided by traders, so that it is now possible to get one's car not only cleaned and polished, but also lubricated. Whether the owner does this work himself or has it done for him, the easier means of maintenance are all to the good. Points that appeal more particularly to owner-drivers, in that they mean less work for them in the garage, are chromium non-tarnishable plating and "one-shot" lubrication, the latter being also good for the car, in that parts which in past years have suffered from neglect will now receive their requisite amount of lubricant.

Sunshine Saloons to be Popular.

Although the open touring car is far from being superseded, saloon cars continue far and away the most popular. Even these are undergoing alteration in design, the sportsman's type, in which a rearward-sloping windscreen is matched by a forward-inclined back panel, being now a prominent design. But though saloons are the fashion, the dry and sunny weather of the past summer has made many motorists long for the open air rather than a stuffy or, alternatively, a draughty atmosphere. Hence most makers are now including in their range a "sunshine" saloon, part of the roof of which can be opened or closed at will.

During the past year there has been considerable discussion as to the respective merits of closed and open cars. To those who use their cars for pleasure purposes and mainly in the spring and summer, there is no doubt that the open model makes a strong appeal, especially in view of the ease and rapidity with which modern hoods can be

raised and lowered, and the fact that the all-weather side panels have been greatly improved. For doctors, however, who have to be out in all weathers all the year round, the saloon car has proved a distinct advantage. At the same time, even medical men will welcome the greater attention that is being given to the provision of a car that can be used either open or closed.

The Trend of Prices.

The show indicates that the prices of cars have for the present touched bottom; there are few instances of reductions, many where prices remain unchanged, and many in which slight advances have taken place. Actually, however, by reason of the detailed improvements that have been introduced and of the inclusion of features hitherto regarded as extras, the cars of 1930 are much better value than their predecessors. Indeed, a few years ago it would have been thought impossible that saloons with eight-cylinder engines would be available, as they are to-day, at so low a price as £395.

The gradual disappearance of some of the successful and popular-priced four-cylinder cars, which have given good service in practice, is reducing the choice of vehicles in the £200–£250 division. Against this, however, is to be set the fact that there is a growing selection of medium-power six-cylinder cars which, even with saloon bodies, are available from £265 to £300, the opinion being widely held that the smoother running of the "six" as compared with the "four" more than compensates for the slight additional cost. The £100 car about which so much was heard a few years ago would appear to be as far off as ever, the cheapest vehicles being the Austin Seven and the Morris Minor, the open four-seaters of which sell at £130. There has been no addition to the range of "babies," which include, in addition to the two just mentioned, the Singer Junior and the Triumph Super Seven, but judging from the number one sees on the roads it is clear that, despite their diminutive size, they meet a real need and are able to hold their own with even the most powerful cars. In the manufacture of "baby" cars Great Britain has led the way, and it is a tribute to British motor engineers that at least one of the little cars is now being manufactured under licence in Germany, France, and the United States.

Cars for Doctors.

It is difficult to single out any cars for the special attention of medical men. There are some who will find that one of the "babies" fully meets their requirements; others, particularly those whose practice lies in very hilly districts, who will require a fairly powerful vehicle. Generally speaking, however, the popular car of next year is likely to be a six-cylinder sunshine saloon of from 12 to 15 h.p., and costing anything from £265 to £395, with a choice of several makes under £300. Although, as already indicated, light six-cylinder cars are rapidly replacing those with four-cylinder engines, there are still many excellent "fours" available, which are well able to meet all everyday requirements in the way of power development and comparatively smooth running, and which, from the point of view of low taxation, ease of management, and low running and maintenance costs, are likely to appeal for some years to come to those of moderate means.

The medical motorist needs no reminder that whatever the class or make of vehicle the essentials from his point of view are reliability of operation, comfort, and smart appearance, rather than luxury and speed. Good all-weather protection and reliable lighting, the latter especially in the case of country practitioners, are also desirable features. Moreover, in view of the fact that doctors' cars have, in the course of a day's round, to be started and stopped frequently, the engine-starting installation, and especially the capacity, trustworthiness, and accessibility of the battery of accumulators used in connexion with it, is a point to be taken into consideration when contrasting the merits of different vehicles.

Nowadays the efficiency and reliability of the chassis components are largely taken for granted, so that the interest of the more wealthy class of motorist will probably centre chiefly in the carriage builders' section of the exhibition, where on over sixty stands one can inspect the latest products of the industry—from the "perky" sports two-seater to the most lordly of limousines, the fittings of which each year become more numerous and sumptuous.

Winter Motoring Requirements.

As usual the galleries are devoted to the display of motoring accessories, the variety of which is so extensive and bewildering that one could spend a day in that section of the exhibition without exhausting its novelties. With winter looming ahead special attention may be drawn to the many varieties of radiator cosies and garage-heating stoves and lamps, the former to keep the engine warm when driving in very cold weather, the latter to prevent freezing up and probable bursting of radiators and cylinders in frosty weather, when the precaution is not taken of drawing off the cooling water when putting the car away for the night. Last winter, despite constant references in motor instruction books and the motoring journals to the special attention it is necessary to give to cars in extremely cold weather, the firms specializing in welding work had more cracked engine cylinders to deal with than ever before. It may be well, therefore, once more to stress the fact that to prevent damage to the engine or radiator it is necessary to draw off the cooling water each night and to fill up again the next morning; alternatively the vehicle must be stored in a warm garage or some anti-freezing medium such as glycerin must be added to the water in the radiator.

Organization of the Show.

In past years there have been many complaints on the part of visitors to the motor show that their detailed inspection of the exhibits was considerably obstructed by the presence on the stands of an unnecessarily large number of salesmen and dealers' representatives. It is therefore satisfactory to know that the organizers of the show have issued a regulation putting a limit on the number of sales assistants that may be stationed on the stands in the car section. All assistants whose presence is authorized will wear a badge which will establish their identity with the make of car with which they are concerned. Although it is hoped that this will to some extent relieve the congestion of former years, those who can visit the show in the mornings will find it the best time to examine the new vehicles in comfort.

Next week it is proposed to continue this review of the main features of the exhibition, and to deal with some of the new models of cars specially suitable for the use of medical motorists.

C. J. W.

WELFARE OF THE BLIND.

AN INTERNATIONAL SURVEY.

We are so accustomed to think of the League of Nations as a body that discusses problems of international politics that we are apt to overlook the work of the League in matters of health. It is, in fact, an active health organization, and evidence of its work in this direction is at hand in the admirable Report on the Welfare of the Blind* which has just been issued. The report arose from a request by the British Government for more general information upon work done for the blind in other countries, and embodies a summary of replies from twenty-six countries to a questionary that was drawn up and issued to fifty-seven countries.

In the main the report deals with the general and economic welfare of the blind, but it includes some interesting material relating to the causes and prevention of blindness. The term "general welfare of the blind" covers all attempts to alleviate the handicap of blindness by education, the provision of literature, social contacts, homes, and the like; "economic welfare" covers vocational training and employment.

Care for the blind is a social effort of comparatively recent date. The first school for the blind was opened in Paris in 1784, the second, in Liverpool, seven years later.

* League of Nations, Health Organization: Report on the Welfare of the Blind in Various Countries. Series of League of Nations Publications, III, Health. 1929. III, 8. Geneva, 1929. London: Constable and Co. Pp. 278. 10s. 6d.

The promoters of these schools believed that with training the blind would be able to earn their own living, but the logic of events compelled them to go further and provide workshops for the employment of their old pupils. A great advance in education followed the relative stabilizing of blind script in the Braille type about 1880, before which, owing to the multiplicity of systems, matters were chaotic. For many years work for the blind was carried out entirely by voluntary effort; gradually Governments intervened, and in many States their activities, especially in relation to the education of blind children, have constituted the most significant advance in the care of the blind that has taken place in recent years. Both in the United States of America and in the British Empire welfare work has been carried much further by the recognition of the State's responsibility for the blind of all ages, the institution of measures for the prevention of blindness, the training of the blinded, and the provision of pensions. During the great war sympathy with war-blinded men resulted in the promotion of measures for the care of all blind persons, whether military or civilian.

Definition of Blindness.

Inquiries were made by the League of Nations into definitions of blindness. Properly speaking, a blind person is one who has no sense of light, but many with such a sense are for all practical purposes blind; they are economically blind, for they cannot earn a living by sight. Again, the definition of blindness in children for educational purposes must be somewhat different from that in adults for economic purposes. This is well brought out by the replies that are reviewed in the report. A child who cannot read the ordinary school books except with difficulty or danger to vision is regarded as blind for purposes of education. Most definitions are based on the presence of some incapacity, though a few countries have adopted a numerical standard. For adults there is an even greater divergence of practice. In Great Britain, Northern Ireland, and the Free State the definition of blindness for the purpose of blind old-age pension has been adopted for all purposes save education. In other countries there does not appear to be any such general uniformity, with the result that there arise all the difficulties associated with the presence of varying standards. For the most part definitions of blindness in adults turn on the capacity to perform work; in the British form occurs the phrase "so blind as to be unable to perform any work for which eyesight is essential"; in the American, "unable to provide himself with the necessities of life." Some Continental countries adopt numerical standards, but these vary from the certification of blindness when vision is less than 6/60 to inability to count fingers on a dark ground at a distance of one metre. In Britain, visual factors alone are taken into account; in the Netherlands regard is paid to other factors, such as health and intelligence. The report stresses the fact that numerical standards cannot be rigidly applied, and that the determination of blindness in doubtful cases, particularly where there are inducements to malingering, may require a high order of ophthalmological skill and experience.

The adoption of a general international standard, or standards, of blindness is discussed; the difficulties involved are clearly recognized, but it is suggested that these are not insuperable, at least in relation to blindness for census and all educational purposes.

The Number of the Blind.

Three methods have been advocated for the discovery of the blind. Of these, compulsory notification is impracticable. The census return has proved to be of poor value owing to the generally recognized fact that reliable information cannot be expected in returns made by, or on behalf of, the individuals afflicted. Experience in Britain suggests that a system of local registration is the most effective way of securing the fullest and most accurate statistics of the blind. A similar procedure is in operation in some States of the U.S.A., and in Canada and New Zealand. Making allowance for varying standards and inaccurate methods of assessing the numbers of the blind, it is estimated that in the countries under review there are, out of a total population of 763 million, 801,443 blind persons, or 104 per hundred thousand; these figures include those of India, where total blindness is the criterion. It is estimated that if unrepresented countries were included and the criterion of blindness were everywhere an economic one, the total of the blind in the world would reach six million. The prevention of blindness is therefore a matter of urgency, and in recent years many countries have done a great deal to this end, particularly by instituting measures for the prevention of ophthalmia neonatorum.

Education of Blind Persons.

In dealing with the blind it is necessary to recognize that there is more variation among them than among normal people; all persons differ from each other in temperament and capability, but the blind differ also in the degree and cause of their blindness. They need, therefore, much individual attention. Particularly is this true of the unemployable blind—that is, of those who, even with assistance, are incapable of an independent economic existence; some of these may, indeed, be able to do some domestic work, but not earn their living in a true sense.

The report proceeds to an examination of the conditions of the infant blind, blind school children, adult blind needing training, employable blind and unemployable and necessitous blind. Contrasts are drawn between the care of the blind child in the home and in what are known in this country as Sunshine Homes. The latter are clearly unsuitable to small countries where the number of blind infants is small, and where parents will give the necessary elementary care. In many countries the State provides for the education of blind children of elementary school age, a matter in which Denmark took the lead in 1858. The tendency is to make the school attendance compulsory. Hardship arises when blind children are compelled to leave home in order to go to a residential school; against this has to be set the future of the child, for the lot of an uneducated blind child is a very unhappy one. Schools for the joint teaching of blind and deaf children are found to be unsatisfactory, the fewer blind children being neglected. The report stresses the need for schools for the mentally defective blind, for their presence in the same school may retard the otherwise normal blind. In most countries the curriculum for the blind is similar to that of the elementary school education, but of late years vocational training has been introduced. One of the most important subjects of training is physical culture, to compensate for the children's inability to join in ordinary games. A blind child finds himself less handicapped in swimming than in many other sports. In England there are troops of blind Boy scouts and girl guides, whilst Worcester College for boys has developed rowing, and even sent an eight to Henley Regatta.

In recent years much use has been made of intelligence tests in guiding the education of blind children. Almost all of them are retarded (some two years) on their first admittance to school, and it is essential to determine whether, and to what degree, this is due to backwardness or mental defect. In this connexion it is desirable that careful records should be made of the general intelligence, progress, and special aptitudes of each pupil, and that these records should follow the child throughout its training. In some schools differentiation is made in the instruction of pupils with different degrees of vision; this is important, especially where the definition of blindness is more comprehensive for children than it is for adults, for a child blind for purposes of education may not be deemed economically blind. Note is made of the myope classes, or sight-saving classes, for children whose sight is defective, but not within the category of blindness. Experience suggests that it may be undesirable to include these classes in schools for the blind; there is a danger that the child with defective vision may, by association with blind children, come to regard itself as one of them.

Vocational Training.

Before undertaking vocational training, with all its trouble and cost, it should be determined whether the child is likely to be economically blind; also, whether he is likely to benefit from the training and become reasonably proficient. A further need is careful adaptation of the course of training to the aptitudes of the pupil. In the United States the training is for the most part given in schools; in this country it is given mostly in workshops. The danger of the school is that it may become academic; of the shop that the pupils may be exploited for commercial ends. The inquiry elicited the fact that there was comparatively little provision for vocational training; in many countries there were facilities for training; but in few was the training obligatory. Provision for higher

education is rare; there are three colleges in England, Germany has one, and Russia one. There is much to be said for the practice of sending blind students to the universities with scholarships, as is done in this country and in the United States.

Occupations.

Music, piano-tuning, massage, handicrafts such as basket and mat-making, chair-caning, knitting-machine work, and the like are much favoured. Of late, many pupils have been taught shorthand and typing, and have entered business. The handicap of blindness usually makes it impossible for blind persons to earn as much as sighted persons in similar occupations; the reduction in their earning capacity is estimated in this country as between 50 and 66 per cent. Though, therefore, the employment of the blind must involve financial loss, their well-being demands that this loss must be faced. The report discusses various methods of meeting the employment needs of blind persons. Special workshops have the advantage that the blind like them; they are their centres of social life. Shops cost a great deal, however; the capacity of the blind is small, and their sickness rate is in excess of the normal; moreover, unless the shop can afford to pay sufficient to attract a competent man to control the business side, the management suffers. The difficulties point to the conclusion that the shop should employ only industrious and competent blind workers; the incompetent and idle should be excluded. There is need, therefore, for better selection for training and more efficient training.

Home workers are found in all countries. Only a few make a success of their work without assistance. The scheme developed in England is cited as advantageous: the workers are trained for some form of handicraft; at certain periods they have refresher courses of training; supervisors visit them and look after their tools and machines; advice is given on marketing and advertising, and in some cases there is co-operative marketing. Such a scheme can best be run from a workshop, which has its own business organization. One of the most striking developments of recent years has been the attempt to bring the blind into ordinary factories and to set them to work alongside with sighted workers. In Germany such employment is compulsory under a recent law making it the duty of employers to engage a certain percentage of war-disabled persons, including the blind; difficulties have arisen, as neither the employer nor the employed realize the extent of the blind man's capacity for work. It is essential for all such experiments that only healthy, self-reliant blind should be employed; it is reported, however, that most employers affirm that blind workers have proved very suitable for certain kinds of work.

The Unemployable and Necessitous Blind.

In this country, where the blind are carefully classified, it is found that two out of every three blind persons are unemployable. The great majority of these are over the age of 50 years, an age at which blind training and new work are usually impracticable. It is believed that these figures are not exceptional.

The needs of the unemployable vary; some few have means or friends; some have State disability pensions, or pensions through insurance or compensation schemes; some are comfortable, others lonely, helpless, and destitute. In the report consideration is given to the various means adopted to help the unemployable blind. It is increasingly common to provide State pensions, and a word of warning is given on the methods of initiating such provision. It appears that the campaigns in the United States of America have been initiated in most instances by blind persons themselves rather than by workers for the blind; in the few States where experienced workers for the blind have taken the lead there has been less abuse of the law, and the blind have been more intelligently treated. If an attempt is made to deal with all the destitute blind who need institutional treatment in special homes for the blind it will be necessary to provide different homes for different classes of the blind. Begging, the immemorial resource of the blind, is legalized in some countries, prohibited in others. Its suppression depends upon the success with which the needs of the blind are met otherwise.

Conclusion.

The report has been issued in the hope that it may stimulate those who are engaged in working for the blind to pool their experiences, and thus point the way to a fuller knowledge of what is being, and can be, done to meet an urgent social problem. Great credit is due to the two British civil servants, Mr. F. R. Lovett of the Ministry of Health, and Mr. G. Hawley of the Department of Health for Scotland, who were responsible for producing the report, and to the social insurance service of the International Labour Office of the League of Nations, which prepared the section of the report dealing with occupational causes of blindness. To members of public health committees of municipal authorities, to medical officers, and to all those responsible for the care of the blind, we commend this report as an admirable and stimulating piece of work.

MEDICAL DEFENCE UNION.

Annual Meeting.

The annual general meeting of the Medical Defence Union was held at the registered offices, 49, Bedford Square, W.C.1, on September 26th, with the president, Sir Herbert Waterhouse, in the chair.

President's Address.

In moving the adoption of the annual report of council for the year 1928-29, the President said that this was the fourth annual meeting of the Medical Defence Union at which he had taken the chair, and on each occasion he had had to report an increase of membership and a continued improvement in the financial position. The fact that the work steadily increased was only to be expected with an increased membership; the union was constantly faced with new questions, and its work did not by any means consist merely in affording a member legal assistance when action was taken against him. By sound advice it could often enable a member to avoid proceedings: often it found that prompt attack might be the best form of defence. The most satisfactory way of handling the various difficulties met with in medical practice could only be known to those who had had considerable experience in such matters, and, in fact, the history of the Medical Defence Union was one long record of the successful handling of every variety of difficulty connected with the practice of medicine.

During the past year allegations of negligence in respect of the treatment of fractures had again been the union's greatest anxiety. In almost every case failure to advise an *x*-ray examination had been the ground of the alleged negligence, and it could not be emphasized too strongly how essential it was, in the interests of all concerned, to advise an *x*-ray examination in all cases of injury to a bone or joint, and, when *x*-ray examination was refused, to preserve some definite record of its refusal; otherwise the defence of the member became a matter of great difficulty or even impossible. During the year it had been necessary to settle out of court an unusually large number of claims against members; the union had done so with the greatest reluctance, and only because the claims could not be successfully defended. Only two actions had been lost, one undoubtedly owing to injudicious conduct of the member after the action was threatened. In the other—the case of Dr. Churcher—the union was unsuccessful in the county court, in the Divisional Court, and in the Court of Appeal. The decision in this case had made it clear that the medical practitioner must be careful to disclaim personal liability when giving an order on behalf of a patient, or he might be held liable at law. Legally the judicial decisions were inevitable, though they might appear unjust and even ludicrous to the uninstructed.

It was impossible, continued Sir Herbert Waterhouse, within the limits of the annual report to deal with more than a small fraction of the work in which the union had been engaged. Various difficulties were brought to its notice daily, and valuable assistance was promptly given so long as a professional principle was involved. It could not be expected that the union should take up a case in which a member was attacked outside his professional occupation, or a case in which a member became involved in a dispute with a professional colleague, unless in very exceptional circumstances. But in cases of disputes between two members of the union the council was always willing to appoint an arbitrator if requested to do so by both members, and provided they were willing to accept his decision as final. In this way several serious disputes had been amicably settled during the past year with no expense to the parties concerned.

Since 1925 the invested funds of the union had increased from some £18,000 to over £40,000, largely owing to the vigilant care of the Finance Committee; the union was therefore in an extremely strong financial position. Its relations with the other English defence society were very cordial, and a standing joint committee of representatives of the two

societies met regularly to discuss matters of common interest and concern. The work of the union was appreciated by the General Medical Council, the British Medical Association, and the various Government departments with which it came into contact, and by the profession generally.

In concluding his address, the president tendered his best thanks to Dr. James Neal, general secretary, and to Mr. Hempson, solicitor to the union, for much valued help and advice during the past year. Frequently it happened that the president was called upon to decide what action, if any, the union should take in an urgent case which could not await the next meeting of the council. In such cases he always consulted Dr. Neal, and frequently Mr. Hempson also. The fact that every decision he had arrived at in such circumstances during his four years of office had been endorsed by the council at its next meeting was good evidence of the value of the advice that he received from these two capable and experienced officers of the union.

The Annual Report.

In its annual report the council recorded that during the year 1,279 new members were elected, a net gain of 799; the total membership on July 18th was 15,794, including 1,339 women. In the course of the report the council deals with cases that came before it during the year under review, and states in general terms the legal issues that were involved. An important decision concerns the legal position of practitioners who are asked to furnish information to medical officers of health in cases of maternal death. The council advised members not to furnish detailed information where there was any possibility of the patient being identified, but following consultations between the British Medical Association and the Ministry of Health the council has been assured that the inquiries in question are so conducted that the position of the attending practitioner is adequately safeguarded.

The confusion that exists, even in the legal mind, on the subject of professional secrecy was illustrated in the case of a member who, having attended a girl in her confinement, was subsequently asked for an interview by a solicitor acting for a client against whom the girl was claiming paternity and aliment. This solicitor contended that doctors were bound, if necessary, not only to give evidence against their patients, but to allow themselves to be precognosced by the solicitor of each party. The union rightly contested this view, and the member was advised not to discuss any matter with the solicitor unless directed to do so by the court.

The unsatisfactory legal position with regard to the right of medical practitioners to be represented at post-mortem examinations was exemplified in a recent case where a medical practitioner, found guilty of manslaughter by a coroner's jury, but subsequently acquitted at the Central Criminal Court, complained that he had not been given an opportunity of such representation. The law provides that the practitioner, if he so desires, may be represented at the post-mortem examination only when a statement has been made on oath that the death was caused partly or entirely by his improper or negligent treatment. The council holds that an accused practitioner should have the right in question whenever any accusation has been made against him.

The solicitors to the union in their report draw attention to a number of cases in which a settlement had to be made out of court, but assure members that their policy is always averse to the settlement of claims so long as there is any real prospect of a successful defence. No encouragement is given to claims which savour of blackmail, or in which it is sought to take advantage of the fact that a professional man may feel inclined to pay rather than face publicity. The solicitors emphasize the fact that once a member has consulted the union he should take no step and make no communication to the other party except on the union's advice; they give added point to their warning by reminding members that the council has the right in any case in which a member has acted on his own account to refuse to be associated with the case any further or to accord the member the help which would otherwise be due to him. They warn members working in partnership that they are not fully protected unless they ensure that each party is a member of the union; even when action is brought against the firm in respect of an act of that partner who is a member of the union the firm is covered only against his part of the liability.

The remainder of the solicitors' report covers a number of the more important cases that concerned the union during the year under review. The cases are extraordinarily varied in character, and their bare recital in print serves to emphasize how many are the hazards of litigation that beset even the most conscientious practitioner.

The report of the council and the financial statement for the year 1928 were adopted unanimously. Sir Hamilton Ballance, Mr. R. F. Jowers, and Sir Herbert Waterhouse, the retiring members of council, were re-elected, and Dr. E. Lewis Lilley of Leicester was elected to fill a further vacancy among the elected members of council created by the resignation of Mr. W. G. Spencer. The auditors, Messrs. Lewis Hardy and Co., were reappointed, and authority was given for the payment of the first-class railway fares (with expenses if detained for the night) of members of council attending council meetings at a distance. The proceedings concluded with a vote of thanks to the president and council for their services during the past year.

MEDICAL SICKNESS, ANNUITY AND LIFE ASSURANCE SOCIETY.

THE annual general meeting of the Medical Sickness, Annuity and Life Assurance Society, Limited, was held at the First Avenue Hotel, High Holborn, W.C., on October 7th, under the chairmanship of Dr. F. J. ALLAN.

Chairman's Address.

The CHAIRMAN, in presenting the report of the board of directors for the year ending June 30th, 1929, said that the Society continued to make steady progress and that the figures presented called for satisfaction all round. The inauguration of the house purchase and practice purchase schemes, to which he referred at the last general meeting, had shown great activity. The loans on property, which were almost all house purchase, had increased from £23,000 to £40,000, while the loans on personal and other securities had risen from £23,000 to £38,000, a large part of which were purchase practice loans on which they had not experienced any bad debts.

The sickness experienced during the year had been very heavy, and was due to the epidemic of influenza during the early part of 1929. The number of influenza claims paid was 384, involving a payment of £6,200. The epidemic had been one of the most serious in the Society's history, and, like previous epidemics, had left in its train all sorts of trouble affecting the health of members.

With regard to the life assurance fund the sums assured steadily rose, and the Society was within a few thousand of its quarter of a million gross. This the directors felt was eminently satisfactory considering the somewhat limited field of the Society's operations. The severe weather of last winter had caused a number of deaths of annuitants, so that there was a reduction in the amounts paid out. The flourishing condition of the Society enabled the directors to recommend the payment of an interim bonus at the same rate as was announced at the valuation in 1927. While management expenses had naturally increased with the increase of business the ratio had decreased from 13.8 to 13.4 per cent. The satisfactory investment of the Society's funds was a matter of vital importance. The board of directors aimed at obtaining as high a rate of interest as was consistent with first-class security. The net rate of increase for the year on the total funds was £4 3s. 2d. per cent. This would have been higher were it not for the investments made twenty or thirty years ago in loans to public authorities; those stood at a very low rate of interest, but were being paid off yearly by a fixed proportion of each loan. The bulk of the Society's investments were redeemable at a fixed rate and at a fixed price. Notwithstanding the depression in all values which began in the spring of the present year the auditors reported that there was £11,786 in the Society's favour in the difference between the aggregate book values and the market quotations.

The Society mourned the death of Dr. de Havilland Hall in January last. He was a foundation member, and had taken a keen interest in its work. After acting as medical examiner for many years he succeeded the late Mr. Ernest Hart as chairman, a position he held for over seventeen years. On his retirement in 1912 he was elected president, and continued as such until the incorporation of the Society in 1920 under the Companies Act.

Dr. Allan added that the present occasion would be the last time he would address them in the capacity of chairman; he had intended giving up the position last year, but the board desired him to continue. He concluded his address by moving that the directors' report and the financial statement for the year be received and adopted. The motion was seconded by Dr. KNOWSLEY SIBLEY.

Dr. HARVEY HILLIARD said he had given notice of four motions, three of which did not appear on the agenda. He had been notified by the secretary that it would be in order to take the three motions on the motion for the adoption of the report. He contended that the motions should have been printed on the agenda of the meeting. He would therefore move that the meeting request the board of directors to prepare a scheme for the insurance against sickness and accident on a permanent contract ceasing at 70, in addition to the contract

of insurance terminating at 65, as at present. He maintained that many members did not read their policies, and were unaware that their benefits ceased on reaching the age of 65.

The CHAIRMAN announced that the board was quite prepared to consider the suggestion.

DR. HILLIARD proposed that a special date be fixed for holding the annual general meeting. This, he said, would enable members to know exactly when the meeting would take place, and they could then put forward any nominations or resolutions in good time. A suggestion by the CHAIRMAN that the date fixed for the annual general meeting should be announced in the medical press six weeks before the date appointed was adopted.

The third motion put forward by Dr. HILLIARD requested the board to resume the practice of issuing a list of members of the Society. This was duly seconded and discussed. On being put to the meeting it was lost by a large majority.

The motion for the adoption of the report was then carried.

Election of Directors and Auditors.

Sir William Willcox and Mr. W. H. Dolamore were re-elected members of the board of directors, and Messrs. Harber, Sturges, and Fraser were re-elected auditors for the ensuing year. On the motion of the CHAIRMAN a vote of thanks was accorded to the staff for their excellent work. The recommendation of the board of directors to pay an interim bonus on all with-profit policies for permanent sickness and accident insurance and life assurances becoming claims during the year July 1st, 1929–June 30th, 1930, was adopted. A motion by Dr. HARVEY HILLIARD, proposing that every director of the Society should resign on attaining the age of 65 years and not be eligible for re-election, was withdrawn with a view to its being brought up on a future occasion.

Vote of Thanks to Chairman.

Dr. MARTLEY said he would like the members to pass a very hearty vote of thanks to Dr. Allan in view of the fact that this was the last annual general meeting over which he would preside as chairman. For seventeen years he had put the best of his force into the work of the Society, and the members had only to look at what the Society was in 1912 and what it was at the present time, when it was trebled in size, to realize some of the changes which had taken place under Dr. Allan's chairmanship. The motion was seconded by Dr. HILLIARD, and carried with musical honours.

Scotland.

Jordanburn Nerve Hospital.

THE lecture theatre of the Jordanburn Nerve Hospital and Psychological Institute, Morningside, Edinburgh, will be opened formally by the Rt. Hon. William Adamson, Secretary of State for Scotland, on the afternoon of Monday next, October 14th. A preliminary account of this new institution was given in the *British Medical Journal* of March 9th last (p. 468). It has been established by the managers of the Royal Edinburgh Hospital for Mental Disorders at Morningside as a voluntary hospital with a complete service for the remedial and preventive treatment of nervous troubles in Edinburgh and neighbourhood. It is not intended to include the treatment of confirmed cases of mental disorder, suitable provision for such maladies being already provided by the managers at Craig House and the West House. The new lecture theatre, which forms an integral part of the organization, has been built at a cost of £8,000 and will be available not only for academic purposes, but also for popular lectures of an educational character.

Crematorium at Edinburgh.

A crematorium was formally opened in Edinburgh by Lord Provost Sir Alexander Stevenson on October 3rd. This is the first provision of cremation in the capital city. Lord Salvesen, chairman of the company, remarked that a Cremation Society had been founded some twenty years ago under the presidentship of the late Sir Henry Littlejohn, and since then they had been working to educate public opinion with a view to obtaining a crematorium such as that now being opened, which would afford a place for the rational disposal of the dead. There had been a great deal of prejudice to fight, including the suggestion that a crematorium might be used as a means for concealing a poisoner's deed, but the speaker considered that in view of the regulations which affected burial and cremation respectively, a murderer or poisoner would be the last person in the world to select cremation for his victim. Not merely must there be a certificate of death from the physician who had attended the deceased, and who must have been present after the individual was dead, but an independent inquiry was conducted by an expert, who must also examine the body. If the official of the Cremation Society had any doubt with regard to the two certificates of these medical men, he was empowered to ask for a post-mortem examination into the cause of death. He remarked further that a great deal of waste, which at present accompanied burial, would be saved by the practice of cremation. The Lord Provost, in declaring the building open, remarked that there were over 6,500 deaths in Edinburgh each year, and the disposal of these remains must sooner or later become a menace to the living so that the corporation would watch the development of the crematorium with great interest. The building has been constructed by the Edinburgh Crematorium Limited, a company formed a year ago with a capital of £13,000. It is situated in the mansion house of Easter Warriston, in grounds of some two and a half acres in extent, and the whole mansion house has been altered by the late Sir Robert Lorimer, R.S.A., to provide a chapel and other necessary accommodation. The incineration is conducted in the lower part of the building by the aid of gas, which provides a temperature between 1,500 and 1,700° F. The Edinburgh crematorium is the nineteenth to be opened in Great Britain, and the number of cremations is steadily rising, the total for last year having been 4,186, as compared with 3,266 for the previous year.

Edinburgh Hospital for Crippled Children.

H.R.H. the Duchess of York, on October 1st laid the foundation stone of the Hospital for Crippled Children, which is to be built near Fairmilehead, on the southern fringe of Edinburgh. The hospital is designed to be a central hospital for the south-east of Scotland, to which other hospitals for orthopaedic treatment in outlying areas will be affiliated. The Earl of Home, chairman of the governors of the hospital, presided. Sir David Wallace, F.R.C.S., remarked that the committee of this hospital deemed themselves very fortunate in having reached the present stage in their work, for a sufficient sum of money had been raised to justify the building of the hospital. An ideal site had been obtained, protected from the north by the Braid Hills, while belts of trees would protect the inmates from strong winds from other directions, and the hospital would face due south so as to obtain all the sunshine that was available. There was a large site of fourteen acres where children would be educated in the open air, and there would be workshops so arranged that patients could work in the open air and sunlight. Manual work would be of great benefit to the patients as it necessitated the use of the muscles, which meant better circulation and which had a beneficent mental influence. It must not be forgotten that major and minor clinics were to be formed throughout the various counties under their scheme, and at the earliest possible time patients who were under treatment in the hospital would be sent out to these local clinics, where further treatment could be carried on in their own homes under careful supervision in close relationship to the central staff of the hospital. The foundation stone was afterwards laid by the Duchess of York, to whom Lord Provost Sir Alexander Stevenson proposed a vote of thanks.

Glasgow University War Memorial.

The new memorial chapel erected at the University of Glasgow was formally opened on October 4th, and dedicated by the Right Rev. Dr. John White, Moderator of the General Assembly of the Church of Scotland. The memorial commemorates 750 students of the University who laid down their lives in the great war. It is an imposing addition to the historic pile at Gilmorehill, and fills a long-felt want in academic life. Built of Blaxter stone, and of simple design, it is as dignified as it is imposing. Inside, the lower walls of the chancel are delicately arched, and within the five arches are contained the black slate slabs bearing the names of the fallen. The organ, which is placed in the north gallery, is the gift of Lord

Maclay in memory of his two sons. A large and representative company attended the dedication service. Following upon prayer and praise, Sir Donald MacAlister, on behalf of the University, performed the ceremony of unveiling the memorial tablets, immediately after which the "Last Post" was sounded from the Stone of Remembrance.

The Housing Problem in Stirling.

Dr. T. Adam, medical officer of health for the county of Stirling, in his annual report deals with the slum question, and pays a tribute to the slum-dweller. He expresses his admiration for the laudable and often successful attempts of many, especially in the mining villages, who, despite unemployment and other adverse circumstances, manage to make their homes look attractive. In his district the new houses provided under the various Housing Acts had been mostly for the more fortunate working classes, but there was a strong feeling in the local authority that the time had now arrived when their housing programme should be so shaped as to do something for the people who were less fortunate.

England and Wales.

Vital Statistics for 1928.

The Registrar-General's *Statistical Review of England and Wales for 1928*, Tables, Part II, Civil, is now obtainable from H.M. Stationery Office (price 5s.). The volume contains statistics of population, marriages and divorces, births, passenger movement, parliamentary and local government electors, and vital statistics of the British Dominions. The estimated population in thousands of Great Britain and Ireland was:

	1927.	1928.	Increase + or Decrease − per cent.
England and Wales	39,299	39,482	+0.5
Scotland	4,892	4,893	+0.02
Northern Ireland	1,253	1,250	−0.2
Irish Free State...	2,958	2,949	−0.3
Total	48,393	48,571	+0.4

The number of marriages solemnized in England and Wales during the year was 303,228, and was equal to a rate of 15.4 persons married per 1,000 persons living. During the three years 1919–21, following demobilization after the war, the rate averaged 19.0, which was the highest recorded since the establishment of civil registration. The rate in succeeding years showed an almost continuous decline until 1926 (the year of the general rate), when it was 14.3—the lowest rate recorded since 1886—while it rose to 15.7 in 1927, and, as stated previously, fell slightly to 15.4 in 1928, comparing with 15.2, 15.3, and 15.2 in the three years 1923, 1924, and 1925 respectively. The births registered during the year numbered 660,267, and were equal to a rate of 16.7 per 1,000 population. This is an advance of 0.1 on the preceding year, the actual number of births rising from 654,172 in 1927, but is presumably a reflection merely of the higher marriage rate for 1927, since the figures for 1929 so far as yet available show a reversion to the previous steady decline in the birth rate. The number of illegitimate births was 29,702, or 45 per 1,000 total live births, a slight increase on those recorded in 1927. The proportion of male to 1,000 female births was 1,044, a slight rise over the figures for the preceding two years. This proportion showed a great increase during the war years and attained a maximum of 1,060 in 1919, since when the decline has been almost continuous; the proportion is now approximating to that which prevailed in the period immediately preceding the war. The number of parliamentary electors on the autumn register was 19,865,649, of whom 11,226,396 were males and 8,640,253 females.

Changes in London Local Government.

The general character and scope of the changes which will follow the application of the Local Government Act to London as from April 1st next have already been explained (*British Medical Journal*, July 13th, p. 67), but figures are now available which furnish a clearer idea of the magnitude of the unified services. Consequent upon the absorption of the Metropolitan Asylums Board and of the work hitherto done by the Poor Law guardians, the staff of the London County Council will be increased by 23,000, and the annual expenditure by £12,000,000. The council will have 40,000 beds for the treatment of the sick and 20,000 for mental cases, in addition to a further 20,000 beds in workhouses which also have been and will continue to be used to a great extent for sick persons. The new duties will as far as possible be fitted into the existing system at County Hall. Thus finance will be dealt with by the present committee of the council; the children in Poor Law institutions will come under the care of the Education Committee, and the ambulance service of the Metropolitan Asylums Board will be assimilated to the council's ambulance service or work in close collaboration with it. To deal with relief a new committee to be called the Public Assistance Committee will be created, and in association with it there will be a number of local committees; those who have served on boards of guardians will be encouraged to be members of these local bodies. For the purpose of this administration the county is to be divided into ten areas, consisting mostly of three—in some cases two and in one case four—metropolitan boroughs. The health services will be dealt with by a reconstituted and enlarged Central Public Health Committee. This committee will deal, among other matters, with the provision, maintenance, and management of hospitals, and for the purpose of hospital administration the county will be divided into five areas, but again following the boundaries of groups of boroughs.

London Hospital Post-Graduate Course.

A number of hospitals are adopting the scheme of holding a post-graduate course for old students during the week of the annual dinner. It is not easy to determine if the post-graduate course is the lure to draw old students to the dinner or vice versa. Perhaps these two attractions have a reciprocal action, for it is certain that wherever it has been adopted the scheme has proved far more successful than its sponsors dared to hope, and both the dinner and the post-graduate course have been attended by a "record" number of old students. The London Hospital, whose annual dinner will take place on October 17th, originally proposed to hold a post-graduate course on October 16th, 18th, and 19th, but so great has been the number of "old Londoners" who have signified their intention of being present that it has decided to hold the course on October 17th as well. For each day of the course there has been arranged a very full programme of lectures and demonstrations, the morning sessions lasting from 10 to 12.45, and the afternoon sessions from 1.30 to 4.30. On October 16th Dr. Russell Brain will give a demonstration on the therapeutic uses of luminal, Dr. W. W. Woods on the causes of sudden death, Dr. S. Phillips Bedson on recent work on vaccination, Mr. Hugh Lett on haematuria, Sir R. S. Woods on the present position of general light therapy, and Dr. John Parkinson on non-valvular diseases of the heart. Mr. W. S. Perrin will give a demonstration of cases treated by radium, Dr. George Riddoch of neurological cases, and Mr. E. C. Lind-ay will conduct surgical operations. The following lectures and demonstrations will be given on October 17th: Dr. W. J. O'Donovan on occupational dermatitis, Dr. Maitland-Jones on infant feeding, Dr. Donald Hunter on the modern treatment of lead poisoning, Mr. Alan Perry on the injection treatment of varicose veins, Mr. H. S. Souttar on radium and its surgical application, and Dr. O. Leyton on diabetes. Ward demonstrations will be given by Dr. R. A. Rowlands and Mr. J. D. Driberg, and Mr. H. S. Souttar will conduct surgical operations. The programme for October 18th includes lectures by Professor A. Ellis on the use and abuse of intravenous therapy, by Dr. P. N. Panton

on pernicious anaemia, and by Mr. Robert Milne on pain in the fore part of the foot; Mr. A. J. Walton will conduct operations; Dr. Clark-Kennedy and Dr. Theodore Thompson will hold ward demonstrations, and Mr. Eardley Holland will give a gynaecological lecture on uterine haemorrhage. At 9 o'clock the same evening, if members of the course desire it, Dr. Ashley Daly will demonstrate methods of anaesthesia. On October 19th Dr. Robert Hutchison will lecture on the dyspepsias of childhood, and Mr. A. J. Walton on the place of surgery in lesions of the upper abdomen; Mr. Russell Howard will hold a ward demonstration. Those specially interested in surgery are invited to attend not only the courses above outlined, but to be present at the operations which will be going on in the theatres each afternoon from 1.30 onwards. The course will be free to old students of the London Hospital, who may obtain further particulars from Mr. Hugh Cairns, London Hospital, E.1.

Courses at the Maudsley Hospital.

As in previous years, arrangements for practical training in psychological medicine will be provided at the Maudsley Hospital, London, during the late autumn and spring. A series of afternoon clinical lectures, illustrated by demonstrations of cases, will begin on Monday, October 28th, when Dr. A. J. Lewis will discuss mental symptoms and their genesis; this series will be continued on subsequent Mondays. Nervous disorders in children will be dealt with by Dr. T. Tennent on the following Tuesdays, and neurotic and psychotic syndromes, by Dr. E. Mapother, on Wednesdays. Dr. J. S. Harris will lecture on Thursdays on the relations of mental disorder to physical conditions. Friday afternoons will be devoted to the pathology of mental disorders and physiological psychology, the lecturer being Dr. F. L. Golla, while Mr. S. A. Mann will discuss laboratory methods and their place in diagnosis, and Mr. C. Geary the pathology of the nervous system. All these lectures begin at 2.30. A clinical discussion on cases in the hospital is held in the wards on Mondays, Tuesdays, and Thursdays at midday; it is free to medical practitioners, as are the lectures previously mentioned. A course of lectures and practical instruction for the diploma in psychological medicine will begin at the Maudsley Hospital next January. The lectures and demonstrations are given in series, and either group can be attended separately. Inquiries should be addressed to the Director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5.

Correspondence.

INDUCTION OF LABOUR.

SIR,—Mr. G. F. Gibberd's very interesting article on the induction of labour in the *Journal* of October 5th (p. 617) shows that there is still dissatisfaction with the methods in vogue. Bladders and bags, bougies and stomach tubes, all seem to have their drawbacks.

Induction of labour is quite a modern procedure; it dates from about the middle of the eighteenth century, and most probably sprang out of the observation of successful spontaneous cases of premature labour in women incapable of giving birth to a full-time child. It was approved at a consultation of the most eminent practitioners in London in 1756, and was "soon after successfully carried into effect by Dr. Macaulay" (Lee's *Clinical Midwifery*, p. 62). Two methods seem to have been employed in those days: separation of the membranes from the uterine wall by means of a sound or a large bougie, and puncture of the membranes by a metal catheter or a stylet. The first of these was evidently dictated by the laudable desire to imitate natural labour as closely as possible, but the latter was justly regarded as much the more certain. Since that time a great variety of methods have been put into practice, but one and all have apparently left something to be desired. May it not be that there is no ideal method suited for all cases and all circumstances?

Regarded from the standpoint of the general practitioner, all methods that involve anaesthesia, risk of sepsis, or much handling are to be avoided if possible; bougies, bladders, and stomach tubes are not for us in the homes of the people. For some years I have been using the combined castor oil method with very good results: castor oil 1 oz. at 7 a.m.; quinine bisulphate 10 grains at 8 a.m.; pituitary extract 1/2 c.cm. at 8.30, and every half-hour thereafter for four doses if need be. But there have been failures, and these constitute irritating experiences which the doctor is most anxious to avoid; they can all be obviated by puncture of the membranes and liberation of liquor amnii, and so far as my experience goes there is nothing whatever of moment to be urged against this practice. It is pre-eminently safe and absolutely sure; it needs no following up with the use of bags, nor does it sensibly prolong labour. Everyone is familiar with the fact that early rupture of membranes—a frequent phenomenon of the castor oil induction—makes little or no difference to the progress of labour. A great advantage of puncture, to my mind, is the immediate relief afforded by the escape of liquor amnii to women suffering from hydramnios, vomiting, or toxaemic states generally, so that even if the onset of labour does not take place for several days the patient herself is made comfortable, and that is a great gain.

If, then, I might offer counsel to a fellow general practitioner, it would be to induce labour in most cases where the intercristal measurement is ten inches or under, and the interspinous nine inches or under; to do it in all cases where the head cannot be easily pushed down into the pelvis; to give "hospital" methods the go-by, and stick to puncture of membranes, with or without castor oil, etc., but always with 10 grains of quinine. I have occasionally regretted the non-induction of labour, but never induction. Like mercy, it is blessed in both giver and receiver.—I am, etc.,

Harston, Cambridge, Oct. 5th. W. J. YOUNG.

MATERNAL MORTALITY.

SIR,—During the last ten to fifteen years midwifery has, through the influence of the Ministry of Health, largely passed into the hands of registered midwives. A survey of the results shows no reduction in maternal mortality. The latest survey shows an increase. Surely this indicates that the solution of the problem does not lie in the complete divorcement of the general practitioner from midwifery practice, as the latest scheme of midwifery service seems to aim at.

As a practitioner of average experience and skill, who has conducted about 1,000 confinements without a single case of maternal mortality, I ought to have a shrewd idea of the principal factors which contribute to a maximum of safety in labour. My cases have occurred in industrial, middle-class, and high-class practice, in institutions, and a few in hospital, so that they are representative for purposes of general averages. I have come to the conclusion that the prevailing system, which encourages a midwife to "book" and attend confinements without supervision by a doctor, is fruitful of all the evils encountered in the practice of midwifery in this country, and is doing more to bring the practitioner into disrepute than anything else. The doctor is called in only when a case is already morbid. If things end not happily the fact is recorded against the doctor who has shielded the blundering midwife. I do not blame the midwife, because she has not been taught to recognize her own limitations; it is the system that is at fault. In my own practice I would refuse to be party to an understanding with any midwife who would look to me to attend at her discretion. Fortunately the system referred to has never been adopted by midwives in this district, with the result that there is the healthiest co-operation between doctors and midwives.

Reviewing briefly the emergency cases to which I have been called in the past, the following in order of frequency have been the causes of failure of the mothers to deliver themselves: (1) debility or disease; (2) psychological

reasons; (3) slight or moderate pelvic contraction; (4) malpresentation or malposition; (5) unduly resistant parts—cervix, or membranes, or pelvic floor. Very much rarer emergencies have been placenta praevia, post-partum haemorrhage, and adherent or retained placenta, etc. In a case of placenta praevia or post-partum haemorrhage, unless the practitioner is on the spot the mother has not one chance in a thousand. In the former case it is of scant comfort to the practitioner called in, and placed perhaps twenty to thirty miles from the nearest hospital, to know that the highbrows advocate Caesarean section as the method of choice in placenta praevia. The only maternal death I have witnessed took place in hospital while preparations were being made for this choice operation in a case of placenta praevia.

(1) *Foulac of Mother due to Debility.*—This is by far the largest group, and therefore the most important in general practice. The expulsive power of the uterus proves inadequate. Secondary uterine inertia has set in before the doctor is called. Delivery with forceps is often necessary after the resumption of normal pains has been patiently waited for. Delivery is easy, and due attention is paid to aseptic technique. There is great tendency to post-partum haemorrhage, but anticipated and encumvented by use of pituitrin. Too often pyrexia follows on the third day or later. On investigation one or two of the following complications are found: anaemia, pyorrhoea, bacilluria, nephritis, gonorrhoea, tuberculosis, or even milk fever or constipation. A general flare-up is feared. Mortality, I am convinced, is highest in this group. The confinement is but an incident in the train of events, the activator of lurking infection already present before labour.

(2) *Psychological Causes.*—The disability is nearly always overcome by use of suasion and sedatives. The use of hyoscine hydrobromide, with or without morphine, gives the happiest results in skilful hands.

(3) *Slight Pelvic Contraction.*—Time and conservation of the mother's strength give the best results. Application of forceps is largely admission of failure on the part of the practitioner. "Failed forceps" should not be heard of in midwifery practice. The desperate remedy of craniotomy should be the only treatment in failed forceps cases. If there is alternative treatment the use of forceps has been wrong to begin with. I have had to do craniotomy once—in a primipara, of course. Forceps, moreover, may cause grave trauma to mother or child or to both, even if there is no perineal laceration.

(4) *Malpresentation.*—In this group difficult manipulation (under deep anaesthesia) is often necessary. The time when correction could have been effected with a minimum of effort and a maximum of safety has long ago elapsed. Contrary to expectation, the anxieties of the case end with the labour, although the chances of infection from without seem considerable. In my experience the same can be said of difficult forceps cases, except where the mother was in a poor physical condition prior to the onset of labour. Trauma *per se* seems therefore relatively unimportant in the causation of puerperal fever and mortality. But trauma is of paramount importance in subsequent disabilities, as the gynaecological surgeon can freely testify.

(5) *Unduly Resistant Parts.*—Time, sedatives, or light anaesthesia bring about the desired results. In a case of resistant perineum where strong pains are present chloroform and forceps may be the best way of preventing perineal rupture, although it is equally true that in the average case of forceps delivery it is time to remove the forceps when moderate "crowning" is effected. Ovarian residue may be of value in this group.

The above series constitute the commonest causes of delayed delivery. Rarer difficulties do happen, but have little bearing on general maternal mortality. The above, however, suffices to show that the great mass of catastrophes is preventable if the expectant mother is under the care of a practitioner from an early date in pregnancy.

The factors which, in order of importance, count in safe midwifery, to my mind, are:

1. Care of the health of the mother throughout pregnancy.

2. Ante-natal examination with a view to finding, in primiparae, (*a*) that there are adequate pelvic measurements, (*b*) that there is no serious disproportion between the foetal head and the pelvis, (*c*) the foetal position. In multiparae with histories of normal deliveries finding of the foetal position as a rule suffices.

3. Post-natal supervision and treatment of any illness present, and the routine use of quinine and ergot in all asthenic cases.

4. Modified supervision until six weeks have elapsed since childbirth.

To leave any case wholly in the hands of a midwife, as the present system will certainly encourage, is surely too great a risk. Abnormalities, whether of health or of pregnancy, are not diagnosable by the midwife until the abnormality has become a menace to the mother's life. Nevertheless, the midwife is a necessity, not a luxury, but the midwife should be subordinate to the family doctor.

It must not be overlooked that in any case of pregnancy the physician's knowledge and intuition, the surgeon's tactile sense, and the accoucheur's manipulative skill may be necessary to circumvent disaster. Given a place and proper encouragement in the preventive aspect of midwifery practice the practitioner will be found to possess all these requirements; but his helpfulness in emergencies will in a great degree depend on his opportunities of attending normal as well as difficult cases.

To compare the mortality rates of to-day in midwives' and practitioners' cases is about as useful as to compare the death rates from common colds and pneumonia. It is useless, therefore, to frame schemes and draw inferences from statistics which at their very source are misleading as to the respective parts played by midwives and doctors in cases which prove fatal. Any scheme likely to prove useful in the reduction of maternal mortality must be born of the genius of the general practitioner, who is at grips with the problem.—I am, etc.,

Ingleton, West Yorks, Sept. 29th. J. MacLeod, M.B., Ch.B.

Sir,—The humorous letter by Dr. D. C. Macdonald, published on October 5th (p. 648), must not be allowed to be taken too seriously. He argues that maternal mortality is due to lack of self-assertion on the part of the general practitioner, and then states that the solution to this problem can only be supplied by the general practitioner. If, Sir, the latter claim is true, then certainly the rest of the profession must see that it is carried out.

Dr. Macdonald's next paragraph states that the old handy-woman was good and experienced, and that the modern midwife is badly taught and badly trained. As one who is interested in the training of pupil midwives I shall be grateful for some instruction from Dr. Macdonald, who has apparently forgotten that many midwives are State-registered nurses, as all should be. He accuses them of breaking Rule 9 of the Central Midwives Board, but has apparently failed in his own public duty by not reporting such instances as came under his notice. He would probably have found that the midwife in question was once a handy-woman, and had gained her status of midwife by reason of practice before the appointed day under the Midwives Act. Next, strong antiseptics are deplored and asepsis exalted in midwifery—just the opposite of opinions expressed at the Annual Meeting of the British Medical Association a few months ago in Dr. Macdonald's own city. As to the supervision of midwives, one point worth bearing in mind is that midwives at least *are* supervised, but not general practitioners! The one hundred or so of inspectors distributed all over the country could perhaps be considered an army burdening the rates by such an observer as Dr. Macdonald. As regards his criticisms of the salary of assistants to medical officers of health, he really should remember that these are rarely above the B.M.A. scale.

After accusing midwives of breaking Rule 21, Dr. Macdonald turns to refer to ill health following confinement. In effect, he states that every effort should be made to lessen pain and shorten the duration of labour by the use of all the appliances at our disposal, and though he does qualify this use by the word "judicious," he is there preaching a dangerous doctrine that one had thought never to hear preached again. It is this very doctrine that is responsible for the ill health that Dr. Macdonald so rightly deplores. He then states that all lacerations, however small (internal or external), should be sutured, and I venture to ask whether he, himself, examines every patient for slight tears of the cervix immediately after delivery and sutures them there and then. I am afraid that some practitioners, even to-day, do not scrub their hands before applying forceps, do not have their instruments boiled before use, decline sterile

towels when offered them, and generally behave in such a manner as to refute Dr. Macdonald's argument.

The problem must be approached on other lines than such polemics. For one thing, there must be recognition and prompt removal for institutional treatment at the first suspicion of infection. I submit that there are to-day indications of a wide-spread absence of immunity to infection. The first letter quoted by Dr. Macdonald shows what immunity used to be enjoyed in maternity cases. Frequent dramatic benefits from autohaemotherapy in many branches of medicine support this thesis, and the work recently published by Professor Mellanby and Dr. Green in the *Journal* of June 1st (p. 984), suggests that this lack of immunity may have a dietetic origin. Finally, it may be noted that maternal mortality from sepsis is definitely less than that due to other causes (1928 returns), which seems to have escaped Dr. Macdonald's notice.

In closing, I would point out that I have adhered rather closely to Dr. Macdonald's own phraseology.—I am, etc.,

Preston, Oct. 6th. R. KELSON FORD, M.D., M.M.S.A.

SIR,—In the *Journal* of October 5th (p. 648), Dr. D. C. Macdonald quotes from a letter I wrote to him recently, and I thank him for this. I felt that modern methods and technique had not improved matters much, or enough, and that a solution of the question of maternal mortality and morbidity cannot be satisfactorily reached on these lines alone. While Listerism has done wonders in the domain of medicine and surgery, its success has not been so manifest in the lying-in chamber. Dr. Macdonald, in recent letters, enthusiastically extolled the use of ovarian residue; he claims for it that the rigors of labour are lessened and the accidents incident thereto are fewer. If this is so, it seems that he is supplying something which the system of the modern parturient woman lacks—something which, perhaps, her own ovaries have failed to elaborate he gives artificially, with apparently marked benefit.

The question arises, Is the present-day woman less efficient to meet the strain and stress of parturition than, say, her grandmother was? I think the answer is in the affirmative, and an inquiry should be made, perchance to get on the right track of the why and the wherefore of this persistent and unyielding maternal mortality and morbidity.—I am, etc.,

Prestatyn, Oct. 5th. W. THOMAS.

RADIUM IN SURGERY.

SIR,—Inasmuch as Mr. Souttar's book was written for beginners, the criticism of it which appears in the *Journal* of October 5th merits far greater publicity than it receives under reviews. Mr. Souttar, in his lectures and writings, leads the reader to suppose that his is an experienced and authoritative voice, and yet he commits himself to statements which can only lead the beginner into a troubled world. While it is true that 0.5 mm. platinum cuts off 99.9 per cent. of beta rays, it is far from true to say that the rest of the irritating rays are negligible, and it is certain that if radium be used with only this amount of screening then a large number of cases will show symptoms of a burn in greater or lesser degree. One of the earliest lessons I learned, both in the laboratory and in the ward, was that 0.5 mm. platinum was not sufficient to prevent the destruction of healthy tissues, and further, that dense sclerosis only occurs after inadequate filterage of the destructive rays. The most difficult point to impress upon beginners is the necessity of a screen of at least 1 mm. platinum, and even with this great caution is necessary. I have seen six cases this year of burns of the bladder and rectum following the use of radium in the vagina in which 1 mm. platinum had been used as a filter. Heyman of Stockholm, who has had a unique experience with radium, employs the equivalent of 1.5 mm. platinum as a minimum, and frequently 2 mm. Many other statements made are unsettled and open to discussion, but the above is of fundamental importance and requires immediate amendment.—I am, etc.,

London, W.1, Oct. 4th. SIDNEY FORSDIKE, F.R.C.S.

SALT DEPLETION BY SWEATING.

SIR,—In view of the correspondence on the above subject in your columns, the following information given in a recent report by the Department of Health of the Commonwealth of Australia, entitled "An investigation into the health of employees in gas-making plants," may be of interest.

Out of the 370 gas workers examined for the purpose of this inquiry, 135 complained of one or more symptoms, and of these 74 complained of cramps. These cramps were usually associated with headache, cough, giddiness, and shortness of breath. It was noted that abdominal cramp sometimes followed the drinking of large quantities of water. In some cases headaches and cramps were experienced at first, but ceased to occur after the men had been employed in gas-making for a certain time. A fireman who had been employed in the horizontal retort house at South Melbourne for twenty years, and who was in perfect health, stated that by rinsing his mouth only and drinking practically no water he had found that he could avoid cramps altogether.—I am, etc.,

London, Oct. 4th. WELDON DALRYMPLE-CHAMPNEYS.

DECLINE IN THE ART OF PRESCRIBING.

SIR,—I consider your article (September 21st, p. 547) very timely. There is not the slightest doubt, with so many firms producing mixtures, tablets, etc., followed by samples and literature galore, that the tendency to resort to these easy methods of prescribing induces the practitioner to ignore the art of writing an original prescription and at the same time gives the patient an easy method of getting the prescription repeated—unless the prescription is definitely headed "Not to be repeated," as it should be in every instance.

In my opinion a most important cause of the decline (and a cause to be deplored) is the tendency to increase formulae, in book form, for national health insurance work. This cause I believe to be a great factor, also, in increasing the cost of the Drug Fund. Personally, I favour the total abolition of all formulae, and the idea of establishing a national formulary booklet is, in my opinion, a move in the wrong direction. It makes prescribing too easy—a rule of thumb—lowers the status of the prescriber before his patient, and throws the art of prescribing to the winds. Thousands of pounds are wasted by their publication and by the excessive prescribing which it unquestionably induces. Thousands of pounds are wasted on keeping a large staff to publish tariff lists (often at once thrown into the wastepaper basket), reminders about drugs, prescriptions, etc., and on inquiring into the cost of each prescription and whether a practitioner is guilty of so-called "excessive prescribing." All this money would be much better spent in maintaining whole-time national health insurance chemists, who could dispense prescriptions at any hour, and not keep patients waiting because some client wants a bar of soap or some scent. At the same time I would trust the panel practitioner to give what he deems as necessary for his panel patient as for his private patient by intelligent prescribing when thrown on his own resources rather than let him be dependent on a booklet. The art of prescribing will then revive. I am sure the cost of the Drug Fund would be less, and more satisfactory to all parties. Whilst some method may—less frequently, I think—be necessary to guard against "excessive prescribing," I would not consider any such charge except after seeing the patient, the whole course of notes, etc., as shown on the medical record card, and hearing the doctor's own views as to the justification.—I am, etc.,

St. Leonards, Sept. 29th. A. G. NEWELL, M.D.

SIR,—I have carefully perused your leader on the above subject in the *Journal* of September 21st, as well as the letter of Dr. Spalding in the issue of the week following (p. 604). I feel strongly inclined to stress a sentence in your leader in which it is stated that "the decline . . . may to some extent be explained by failure on the part of the medical schools and of the various examining bodies to

give due weight to the importance of the subject." It would certainly appear as if the present educational system is more defective than its product. Without doubt the medical man newly armed with degree or diploma starts practice with a serious handicap in the realm of therapeutics and applied pharmacology, and for this reason falls a ready prey to the use of proprietary preparations and compressed "ready-mades," empirical prescribing following as a matter of course.—I am, etc.,

Arnside, Westmorland, Oct 7th D. M. Macdonald.

WOMEN MEDICAL OFFICERS AT V.D. CLINICS.

Sir,—The council of the Medical Women's Federation at its recent meeting considered the question of the appointment of women medical officers in connexion with clinics or hospitals for the treatment of venereal disease. It was the strongly expressed opinion of the council that there is a definite desire on the part of many women patients for treatment by practitioners of their own sex. The following resolution, which I am desired to bring to your notice, was unanimously passed:

> The Medical Women's Federation urges that the medical officers treating female venereal disease cases, whether in hospitals or clinics, should be women medical practitioners, where and whenever such practitioners are available.

—I am, etc.,

Violet Kelynack,
Medical Secretary.

Medical Women's Federation, 9, Clifford Street, Bond Street, W.1, Sept. 30th.

X-RAY DEPARTMENT DANGERS.

Sir,—The comments of Dr. J. R. Riddell and Dr. L. A. Rowden upon my letter in your issue of September 7th (p. 478) necessitate further encroachment on your space.

Dr. Riddell courteously sent me a copy of his letter which was published on September 28th (p. 599), and on inquiry I find his first contention correct. The first valve apparatus was exhibited in November, 1925, and was installed in the German Hospital, London, in December, 1925. The apparatus I used for private work was installed in January, 1927, and the firm responsible for the installation informed me that these were then the only two examples of such apparatus existent in Britain. The installation of Dr. Riddell's apparatus in October, 1926, unknown to the firm installing that which I used, was therefore the prior installation for private work. This does not, however, materially alter the object of my statement, which was for the purpose of showing that, while I am a critic of the value of four-valve apparatus, I was a very early user of this, and therefore my criticism is based on experience and not conservatism.

I am unable to agree with Dr. Riddell's contention in his last paragraph, since, unlike valve apparatus requiring constant attention, the mechanical apparatus requires attention very rarely, perhaps once in two or three months. Actually I have known one apparatus, doing very heavy work, which was not even inspected for two years; this shows that the need of attention is very small with the mechanical rectifier. Any possibility of the rectifier getting out of phase is removed if it is correctly manufactured and pinned before delivery, when it is, once for all, determined for the whole life of the apparatus.

To avoid further misunderstanding I would say that the valve apparatus which I criticize is that employing four valves connected in what is termed the "Gratz connexion." The so-called "constant potential" valve apparatus has certain advantages over other apparatus as regards the spectral emission of x rays. This employs two valves and condensers, and, whereas the rectification can be attained mechanically, owing to the tendency of the condensers to discharge backwards across the rectifier, valve rectification is usually preferable.

Concerning Dr. Rowden's letter on September 28th (p. 599), I fail to see why Dr. Finzi's name has been introduced, since it certainly did not appear in my own letter, which was only concerned with pointing out that the suggestion in your article of August 17th as to lining a valve apparatus cabinet with lead rubber was, on the score of economy, merely another disadvantage of this apparatus, which only has application where space is restricted, and is not applicable where the installation can be arranged in two or more rooms—always a preferable course. My remark that the mere possession of x-ray apparatus did not constitute a radiologist was certainly not applicable to a radiologist of Dr. Finzi's eminence, but was directed against the wholesale installation of x-ray apparatus by many having no specialized knowledge of radiology, apparently purely as a further source of income. Poor work is then turned out, and, in consequence of many errors of diagnosis, radiological science is brought into disrepute. I could give many examples of errors in such amateur radiological work. The difference between skilled and amateur radiological work is exactly that between skilled specialized surgery and occasional amateur surgery as judged by the end-results.

No one will question Dr. Rowden's demand for a sound knowledge of pathology, medicine, and surgery. Like fire, radiology is a very good servant but a very bad master, and its findings have to be interpreted in conjunction with clinical findings. Where this is done errors are not so liable to occur in consequence of artefact appearances, and radiology is not brought into disrepute. It is equally obvious that for the best results a knowledge of the physics of x rays is equally imperative, and the requirements of the D.M.R.E. make this need obvious. The only point on which I disagree with Dr. Rowden is the suggestion that, instead of "long experience," "extensive experience" should be substituted, since the one need not necessarily be the same as the other.—I am, etc.,

Forest Gate, E., Oct. 1st. Bernard Leggett.

Medico-Legal.

FAILURE TO COMPLY WITH DANGEROUS DRUGS REGULATIONS.

At the Marylebone police court, on October 1st, before Mr. Powell, Dr. Reginald George Karn of Beaumont Street, W., was fined £10, and Dr. Frederick Stuart of Charles Street, Knightsbridge, £20, in each case with ten guineas costs, for contraventions of the Dangerous Drugs Consolidated Regulations, 1928. It was proved that Dr. Karn had failed to enter in a register a quantity of heroin, and Dr. Stuart a quantity of morphine sulphate and heroin, obtained from a firm of chemists. In imposing the penalties, however, the magistrate said that one thing was clear: there was no suggestion against either of these medical men that the regulations were infringed for the purpose of any malpractice in administering the drugs. In one case the offence arose through carelessness and slackness, in the other through ignorance.

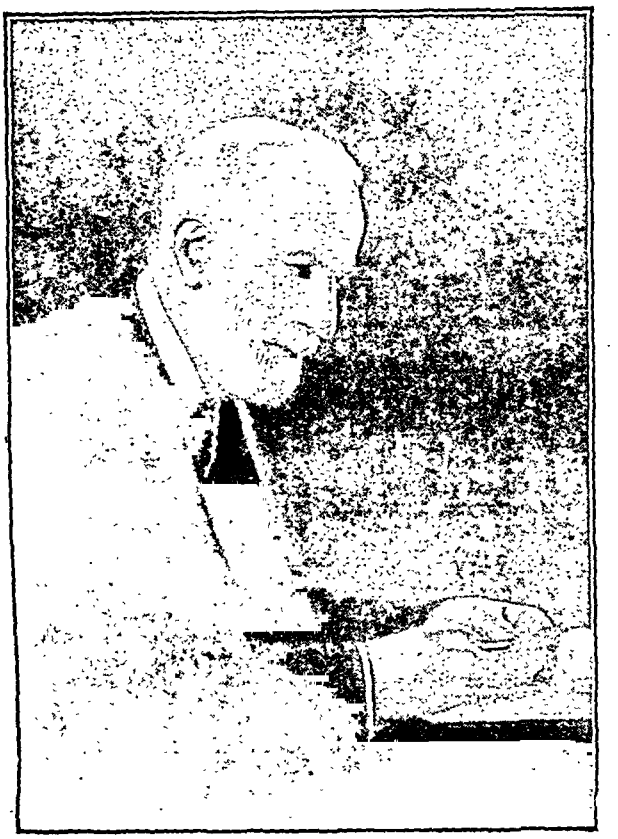
Mr. Vincent Evans, for the Director of Public Prosecutions, stated that in June last a Scotland Yard inspector, making inquiries as to a quantity of drugs supplied to two persons, a man and a woman, found a number of prescriptions signed by one or other of these practitioners, and in several cases the body of the prescription had been filled in by a different hand from that of the signature. Dr. Karn, on being shown certain prescriptions, admitted that they were signed by him, and that the body of the prescription was in the handwriting of the patient. Ten orders for drugs obtained for professional use, although signed by him, were in the handwriting of one of the patients, and although the orders were marked "For professional purposes," the drugs were obtained for, and sent direct to, the patient. Dr. Karn had apparently taken over these patients from Dr. Stuart, and had attended them for three months. Dr. Stuart, with regard to certain of the prescriptions signed by him, admitted that they had been filled in by the patient. There were thirty occasions on which drugs were supplied to Dr. Stuart, but only ten had been recorded by him. Dr. Stuart put down his neglect to overwork and illness, while Dr. Karn pleaded that he himself was purely an anaesthetist, not in the habit of prescribing dangerous drugs, and was in complete ignorance of the detailed regulations. Mr. Vincent Evans agreed that the prosecution was not in a position to refute the evidence of Dr. Stuart that the drugs were necessary for the treatment of the two persons concerned, and the magistrate said that he himself would assume that that was so. He regarded Dr. Stuart's as the more serious case, because Dr. Stuart knew of the necessity of keeping a register, and in his case the offence had been going on for many months.

Obituary.

SIR T. JENNER VERRALL, LL.D., M.R.C.S.,

Past-Chairman of the Representative Body, British Medical Association; Consulting Surgeon, Sussex County Hospital.

We have to announce with sorrow the death, on October 4th, of Sir Jenner Verrall, for very many years a leading figure in the British Medical Association, who won the esteem and warm personal regard of all with whom he came in contact. Though he had not been physically the same man since an operation, his mind remained alert, and he felt keenly the relinquishment of active work in the Association and on the General Medical Council.



T. Jenner Verrall

Thomas Jenner Verrall was born on October 13th, 1852, and belonged to a family which has been continuously associated with Sussex affairs for generations. His father, Henry Verrall, J.P., was clerk to the magistrates and a solicitor in Brighton, and prominent in all local matters; he was colonel of the 1st Volunteer Battalion Royal Sussex Regiment, a position later held by his younger son, Hugh. Sir Jenner also took a warm interest in the regiment, and became captain (honorary major), on reaching which rank he retired. His elder brother was the well-known classical scholar, Arthur Verrall, Litt.D., Fellow and Tutor of Trinity College, Cambridge, and later King Edward VII Professor of English Literature in the University of Cambridge. Jenner Verrall was educated first at a private school in Brighton, and then at Marlborough College. He began his medical studies at the Sussex County Hospital, and completed them at St. Bartholomew's Hospital, obtaining the M.R.C.S. and L.R.C.P. diplomas in 1876. He then went to practise at Brighton, becoming surgeon and, later, senior surgeon to the Sussex County Hospital, and on his retirement was elected consulting surgeon. He was recognized by his colleagues in the district as a good clinician and a very good operator. Had he wished to do so he could have made a name as a surgeon, although the more strictly scientific side of medicine did not much attract him; he was perhaps too literary in his tastes and habit of mind. Always keen on English literature and the English language, he was very well read, and his scholarship revealed itself in everything he spoke or wrote. He was also much interested in architecture (especially ecclesiastical) and in history, and enjoyed all open-air pursuits.

A man of Verrall's outstanding character and gifts would have made his mark in any walk of life, and it was fortunate for our profession that from an early stage in his career he chose to identify himself with its organization, and after retirement from active practice devoted his energies to public work in the interests of his fellows. At first locally, and afterwards in central affairs, he gave himself heart and soul to the service of the British Medical Association. It is unlikely that any one member has ever been called upon to serve in so many different capacities. The record opens more than forty years ago with his appointment as district honorary secretary for East Sussex in the South-Eastern Branch, followed four years later by secretaryship of that Branch, which he held until 1904, afterwards serving as its vice-president and president. In the Brighton Division he held office as secretary, vice-chairman, and chairman; when he went to live at Bath in 1912 he was promptly elected on to the Bath and Bristol Branch Council; and again, on his removal to Leatherhead, the Surrey Branch Council made him a member. But all this executive work at the periphery formed but a small part of what Verrall did for the Association and its members, and, through the Association, for the profession at large and the public. At one time or another he was a member of thirty committees or subcommittees at headquarters, serving on some of them for many years in succession. Apart from his chairmanship of the Central Medical War Committee, he had been chairman of four important committees in London—the Dominions, the Organization, the Medico-Political, and the State Sickness Insurance Committees—and he served on the Central Council of the Association almost without a break from 1893 to the day of his death.

Whenever a big project appeared on the horizon, or an urgent public question arose, or delicate negotiations had to be undertaken, the natural thing was to put Verrall on the appropriate body. Thus, to name but one of many occasions in thirty years, he was a member of the Constitution Committee set up in 1900, which formulated the scheme for reconstruction of the Association's machinery. In due course the Representative Body, which resulted from that scheme, elected him its Deputy Chairman, and later its Chairman. His tenure of these two offices coincided with the introduction of the National Insurance Bill, its passage through Parliament, and the beginning of medical benefit under the new Act. All who took part in those stormy Representative Meetings between 1911 and 1914 will remember the tact and courtesy and the statesmanlike poise of Jenner Verrall in the chair. To mark its sense of his worth, and its gratitude for his work, the Council awarded him the Association's Gold Medal of Merit in 1914, and six years later the Representative Body, by unanimous vote, made him a Vice-President of the Association. In 1921 he was President of the Section of Medical Sociology at the Annual Meeting in Newcastle, and in 1924 he was chosen to visit Canada in company with

Dr. Cox as envoy of the British Medical Association to the Canadian Medical Association. During the Annual Meeting of 1914 he received the honorary degree of LL.D. from the University of Aberdeen, and in May, 1919, the honour of knighthood was conferred on him in recognition of his services as chairman of the Central Medical War Committee during the previous four years, in which capacity he greatly assisted the Army Council and the Ministry of National Services in obtaining medical officers for the Army, Navy, and Air Force.

This outline of Sir Jenner Verrall's work for the profession may fittingly close with a brief reference to his membership of the General Medical Council. He became a direct representative for England and Wales on January 1st, 1912, and at the end of each term of office his fellow practitioners showed their trust in his wisdom and discretion by re-electing him. It was with great regret that the Representative Body of the British Medical Association heard last July that he would not seek further re-election at the end of the present year, and a motion recording high appreciation of his eighteen years' service on the General Medical Council and in other capacities was carried with acclamation. The resolution ended with the hope that he would long be spared to increase the debt owed to him "for counsel, for inspiration, and for leadership."

Sir Jenner Verrall married in 1882, and is survived by his widow, two sons, and four daughters. His eldest son, Mr. Paul Jenner Verrall, F.R.C.S., is orthopaedic surgeon to the Royal Free Hospital; his second son, Christopher, an officer in the Royal Sussex Regiment, was killed in action in December, 1914. Sir Jenner Verrall's funeral took place at the Parochial Cemetery, Brighton, on October 7th. It was very quiet, being practically a family affair, but the Council of the Association was represented by the Chairman of the Representative Body, the Treasurer, Mr. E. B. Turner, and the Medical Secretary, while the Sussex Branch was represented by Mr. Nethersole Fletcher, senior surgeon to the Sussex County Hospital, and Mr. George Morgan, an ex-president of the Branch, Dr. Helen Boyle, and Dr. L. A. Parry, honorary secretary.

Dr. Mark H. H. Vernon (Horsham) writes:

My first recollections of Thomas Jenner Verrall carry me back to a mathematical classroom about 1867 or 1868 at Marlborough. Seeing me in difficulties about sums or a problem in Euclid, Verrall, unasked, gave me efficient help. His kindly action laid the foundation of a friendship which lasted through a fairly long life. His school career was steady and creditable, though not marked by any special brilliancy in either work or games. After leaving Marlborough we found ourselves together as pupils at the Sussex County Hospital at Brighton, where we had the advantage of much good clinical teaching from the staff. At that time a period of pupilage at Brighton counted as part of the four years' professional course before taking a qualifying examination. Whether his time at Brighton counted or not, he made good use of it. After leaving Brighton we saw much of each other at St. Bartholomew's. He was clinical clerk to Dr. Andrew, and dresser to Sir Thomas Smith when I was that surgeon's house-surgeon. In that capacity he was one of the best, always reliable and ready for any amount of work at any time. The qualities which made him a ready helper at school were ingrained in him, and he loved his work. After leaving Bart's he became a valued member of the surgical staff at the Sussex County Hospital. Working as I have done most of my professional life in Sussex, I often came in contact with him, and had the advantage of his good counsel. He did much good work for the British Medical Association in Brighton and the county of Sussex, and I have had opportunities of admiring his conduct in the chair at B.M.A. meetings. Verrall's home training and personal character inclined him to take a serious view of life and its responsibilities, and to avoid its frivolities, though he could be cheery and genial. He set himself a very high standard of life and acted up to it, and he spared no pains to help others to attain to it. He was faithful in all things.

Mr. E. B. Turner, F.R.C.S., writes:

Verrall took office as Chairman of the Representative Body in very troublous times. The fight over the Insurance Bill was raging and necessitated very frequent meetings, so that in one year he probably presided over more sessions of the Representative Body than any other Chairman in his three years of office. It was a difficult and delicate task which he had to handle—controversy and feelings ran high, and his tact and personality often saved the meeting from disaster. At the same time he was chairman of the State Sickness Insurance Committee, to which the Representative Meeting entrusted the formulation and definition of the policy of the Association with regard to the Bill. He carried through this exceedingly strenuous and exacting business with such success that all of his colleagues on that committee entertained him to dinner to celebrate the presentation of its report and the discharge of its reference. In 1915, the last year of his chairmanship of the Representative Body, resolutions were introduced and carried through constituting a "Central Medical War Committee," which might deal with the question of the staffing of the new armies with civilians as medical officers, and do all that was possible for the Association to accomplish in aid of the country during the war. I proposed Verrall as one of the British Medical Association members of that committee, and as chairman of it at its first meeting. On the passing of the Military Service Act this committee (which had worked with the Committee of Reference appointed by the Royal Colleges to deal with the "consultant" class of practitioners) was constituted the "Central Professional Committee," and was empowered to deal with the enrolment and appeals of the whole medical profession. During all the years of the war, and afterwards when demobilization was taking place, Verrall came up from Bath times without number, and gave of his very best to the work. The success of this committee's efforts is generally admitted, and it probably stands out as the best work the Association has ever accomplished for the good of the whole medical profession. This success was mainly due to the great and unselfish work of its chairman. As one who was associated with him in all these activities I can testify to the exceeding value of his work and personality to the Association, the profession, and the nation. He was clear, eloquent, witty, and explicit, absolutely single-hearted and straight, with, above all, the saving grace of humour. A great gentleman has passed over; it will be long ere we look upon his like again.

Dr. H. B. Brackenbury, Chairman of Council of the British Medical Association, writes:

When I first became a member of the Council Sir Jenner Verrall was Chairman of the Representative Body. To an inexperienced member it appeared at that time that in Sir Jenner Verrall and in Dr. J. A. Macdonald, then Chairman of Council, lay embodied most of the wisdom and experience that were necessary to guide the Association on a voyage that promised to be by no means smooth. This appearance was not wholly true, for there were others; but it truly indicated the impression made by the character of the man, the whole-hearted devotion which he continuously showed to the interests of the Association and profession, and the wisdom and experience which he brought to bear upon all their affairs. Even before those days, and certainly ever since, this personality of his, this devotion, zeal, and wisdom, have never failed the profession. He was constant in his duty and invaluable in counsel, and I, like many others of his colleagues, have had personal experience of his careful and kindly help in many a difficulty. I cannot speak at first hand of his work in connexion with the Central Medical War Committee, but as a direct representative on the General Medical Council he was equally helpful and devoted. He was an interesting, friendly, and lovable man, and an adept at verbal and technical, as well as more fundamental, criticism. His passing will leave a great gap at meetings of the Council, committees, and Representative Body of the Association, but he must have been gratified to be able to continue his work there till the last, and to die, as they say, in harness.

Sir Robert Bolam writes:

The British Medical Association loses, by the passing of Sir Jenner Verrall, an influence in its inner councils of a rare quality not easily, if ever quite, to be replaced. He had an intimate knowledge of Association affairs during long years of service in some of the most anxious and unprecedented times that a professional organization has passed through. His was the hand that guided the Representative Body through the difficult years when the echoes of the strife over health insurance still lingered and the turmoil of the great war involved the profession of medicine. Perhaps of all his work the marshalling of medical manpower by the Central Medical War Committee will stand as the finest achievement. In the chair of that committee there was need of all the qualities which in Jenner Verrall were so fully found. He has left a profound impress, too, on the organization of the profession he loved to serve. And there will remain with those who were privileged to work with him the exhilaration of his blithe and ever-youthful spirit, the sheer joy of his fluent speech and apt quotation, the intellectual pleasure of his balanced arguments, and, beyond all, the memory of his fearless courage.

Dr. C. E. S. Flemming (Bradford-on-Avon) writes:

Verrall dead! It seems impossible when we think of the quick mind, the cheery welcome, the bright eye that we knew so short a while ago at Manchester—yet at the Representative Meeting, after the Chairman had delivered a eulogy on the work of our retiring representative on the General Medical Council, Verrall, shaken with emotion, three times got up to reply, three times sat down, unable to say a word. Those who witnessed that poignant scene must have felt that he at any rate had at that moment seen coming up the valley the great shadow that was all too soon to hide from his sight for ever the world that he loved and served so well; the days that were a joy to him and all that knew him. At the same time they must, too, have realized what his work for the profession meant to him and what he was to the profession. For several years he lived in Bath, where medical men quickly came to recognize him as a man above most. With his fluent speech, ready wit, and fearlessness in debate, and his wise counsel, he soon became the trusted friend and guide of the profession in the neighbourhood—all men loved him. He lived in Bath during the days of the insurance fights, and it is easy to realize how valuable his help was then, for he was a man of high ideals and had withal a logical and practical mind. To all who had the privilege of knowing him intimately the first impression on hearing of his death must have been—there is gone a very dear friend, a wonderful companion who loved life and all that was good in it; gone a great heart and a fine courage. But there is left a happy memory, a lasting inspiration. Could he speak, his last words would be "Carry on."

The Medical Secretary sends the following tribute:

I write this under a deep sense of personal loss, for Sir Jenner Verrall was not only the doyen of our Council, a brilliant man, and a most active member of our Association, but a close personal friend and a never-failing source of inspiration and joy to me. It is thirty years since I first met him at an Annual Meeting of the Association, but I only got to know him when he and I were members of the Constitution Committee in 1900, which not only greatly changed the constitution of our Association, but directed its activities into new channels. He sat on that committee as one who was already a member of Council, professing, as he always did, conservative leanings of a pronounced type. But then, as always, up to the very last, he was open to new ideas and, once convinced, proved of great help in getting them adopted by the general body of the Association. From the first I was an admirer of the wit and brilliance which were so characteristic of the man, but gradually I got an insight into the emotional side of his character and a knowledge of his sterling qualities, and was proud to become a friend as well as a colleague. He affected to be a confirmed pessimist. Very frequently he came into my room and announced, when asked how he was, "I am very depressed. It's a *poor* world." But he could not keep it up for long, and there is no man who has brought inside the walls of the B.M.A. headquarters more of the sense of the joy of life and the "worthwhileness," as he called it, of good work. And in this I speak for all my staff who came in contact with him.

I remember him with deep thankfulness as a leader and comrade in many a dark and anxious time, particularly in connexion with the early days of national health insurance and with the work of the Central Medical War Committee. He had not the masterfulness or the prompt decision of a J. A. Macdonald, but what a combination they made, and how each admired the gifts of the other! Elsewhere will be found some indication of the offices Verrall held in the Association and in other professional bodies, so I need not dwell on that side, except to point out what a tribute it is to the British Medical Association that a man of his calibre, easy in circumstances, and who could undoubtedly have made a mark in either local or national politics, chose to devote his energies to our Association. For there is no doubt about it, the B.M.A. was the apple of his eye, and there was nothing we could ask him to do that he would not do with all his might.

Verrall was always ready in debate—indeed, his weakness (and he knew it) was too great a fluency. I saw somewhere a description which I thought applied with peculiar fitness to Verrall, "His thought worked best along a kind of paper-chase track of vivid words laid for the pursuing intellect by the fore-running tongue," and I remember how he laughed when I tried it on him. But at his best he was a real orator, by which I mean that, given the occasion, he could impart into his speech deep feeling and indeed passion. The finest example I ever heard was at Ottawa in 1924, when he and I were on our mission to the Canadian Medical Association which resulted in the affiliation of that body to the B.M.A. The occasion was the dinner of the Canadian Medical Association, at which were present many prominent Canadian laymen, including that eminent orator and statesman Sir Robert Borden. In replying to the toast of "The British Medical Association," Verrall rose to great heights, bringing out his faith in our profession, in our Association, and, above all, in the destinies of the British Empire, in a way which deeply moved his audience. Verrall made many friends for himself and our Association in Canada, and I know his loss will be deeply felt by them.

Greatly as I feel his death, I am even more conscious of the value of his life and personality to our Association, and I am sure that is the way he would like to be thought of just now. He was, I think, the one who suggested the two beautiful phrases which adorn our Memorial Gates: "Faithful hath been your warfare" and "Memory and praise." Though these words were chosen as a tribute to our fallen members, they can very appropriately be applied to one who gave abundantly of great gifts to the service of his fellows in the medical profession. How moved he was by the resolution which the Representative Body passed at Manchester, and how glad we must all be that we did not wait until he was gone, but told him, in his presence, how proud and how fond we were of him. He was a great B.M.A. personality; an upright man in whose presence you simply could not say a mean or a base thing; a fine specimen physically and mentally of the British gentleman; and there is not one of us who had the privilege of working with him who is not a better man for his friendship.

[The photograph reproduced is by Herbert Lambert, Bath.]

The following well-known foreign medical men have recently died: Professor Ardin-Delteil, dean of the Faculty of Medicine of Algiers; Professor O. Kutvirt, director of the Czech oto-rhino-laryngological clinic of the Karl University at Prague, and founder and president of the Czech Oto-laryngological Society; Professor René Fortier, who had held the chair of hygiene and paediatrics at the Quebec Faculty of Medicine since 1894, aged 63; Dr. C. Papastratigakis, an eminent neurologist of Athens; and Dr. Amédée Pugnat, professor of oto-laryngology at Geneva, aged 55.

WILLIAM GORDON, M.D., F.R.C.P.,

Consulting Physician to the Royal Devon and Exeter Hospital, and the West of England Eye Infirmary.

WITH deep regret we have to record the death, at Exeter, on October 1st, of Dr. William Gordon, after an illness of a few weeks. His passing takes from that city her most distinguished physician, whose fame as a consultant was widespread in the West of England. The death, in July, of his brother, Mr. T. E. Gordon, president of the Royal College of Surgeons in Ireland, moved him very deeply, and some weeks later he contracted an influenzal infection from which he failed to recover.

William Gordon was born in County Tyrone, in 1863. After winning an exhibition and a scholarship at Trinity College, Cambridge, he obtained a first class in both parts of the Natural Science Tripos; he then continued his medical education in Heidelberg, and in University College Hospital, London. He received the diploma L.R.C.P. in 1888, and graduated M.B., B.Ch.Camb. in 1890, proceeding M.D. four years later. In 1891 he became M.R.C.P., and was elected F.R.C.P. in 1903. Exeter then became the centre of his professional life, and his scientific skill and clinical wisdom rapidly won for him a great reputation as an expert diagnostician in cardiac and pulmonary conditions. The special interest he took in pulmonary tuberculosis—then one of the least hopeful spheres of medicine—led to an invitation from the Devon County Council to investigate the cause and effect of this disease as regards that county. He subsequently made a close study of the influence of strong, prevalent, and rain-bearing winds on the incidence of phthisis; the report and the statements which he published later attracted considerable attention and provoked no little discussion. The problems concerned with the diagnosis and treatment of cancer were also of special interest to him. Among the appointments he held in the Exeter area were those of physician to the West of England Eye Infirmary, and of the Exeter Dispensary in Queen Street. For many, however, his memory will be most closely associated with the outstanding work he carried on at the Royal Devon and Exeter Hospital, where, until last year, he was senior physician. Always a scientist, he was foremost in adopting the most effective scientific methods in his clinical work, and he made this hospital a leading centre of medical progress in the West of England. On his retirement last year under the age limit, he was appointed consulting physician to the hospital. During the war he acted as medical officer of No. 1 Temporary Hospital at Exeter from October, 1914, to February, 1918. He contributed numerous articles to British and American medical journals, and at the congress in Zürich of the Royal Institute of Public Health last spring he read by request an article on phthisis.

Dr. William Gordon was a most distinguished member of the British Medical Association, and his work under its aegis was soon recognized as being of national importance. He was a member of the Council from 1893 to 1897, and from 1896 to 1898 he was chairman of the Parliamentary Bills Subcommittee on Army Medical Reform; in this capacity he played a prominent part in the founding of the Royal Army Medical Corps. Since the early eighties the British Medical Association had endeavoured to relieve the then existing Army Medical Service of the serious incubus which prevented its attracting the better-trained members of the profession. Year after year the fight continued, but little progress was made, despite the efforts of Mr. Ernest Hart, then Editor of the *British Medical Journal*. Dr. Gordon threw himself into the campaign, and drafted a comprehensive and convincing report embodying the history of the whole question and the reforms necessary. Lord Lansdowne, the then Secretary of State for War, received a deputation from the British Medical Association, and Dr. Gordon also visited him subsequently in order to ensure the whole position being made clear. This resulted in a Royal Warrant being promulgated in June, 1898, establishing the right of medical officers in the army to all the ranks open to military officers, and creating the Royal Army Medical Corps. Dr. Gordon's triumph in this respect was recognized officially by the British Medical Association, and at the Edinburgh Meeting in July, 1898, the President, Sir Thomas Grainger Stewart, publicly congratulated him, and expressed the thanks of the Association for his fine achievement. Dr. Gordon also rendered valuable services as a member of the Constitution Committee of the Association, which came into being in 1900, and brought about far-reaching changes in the ensuing two years. His interest in such matters did not, however, distract his attention from the needs of the Association in the West of England; he served as honorary secretary of the South-Western Branch from 1895 to 1897; he was a member of the Branch Council from 1898 to 1923, and again from 1927 to 1929; he was president of the Branch from 1924 to 1925, and vice-president from 1928 to 1929. He gave the utmost support to the Exeter Division; he was a member of the Executive and Ethical Committees from 1915 to 1921, vice-chairman from 1920 to 1922, and chairman the following year. When the British Medical Association met at Exeter in 1907 he was president of the Section of Medicine, and in 1913 he was vice-president of the Section of Climatology and Balneology at the Annual Meeting at Brighton. Dr. Gordon was a Fellow of the Royal Society of Medicine; Hyde Lecturer in 1913; president of its Balneological and Climatological Section from 1915 to 1917; and vice-president of its Section of Medicine from 1923 to 1925.

Mr. RUSSELL COOMBE, F.R.C.S., sends the following tribute:

I have been asked to write a few personal notes about Dr. Gordon. It is not easy to do this about one whom one has known for nearly half a century, for I first made his acquaintance at Cambridge in 1882. During the forty years he has been in Exeter we have always been close friends, and for the last thirty years on terms of brotherly intimacy. He was the most loyal of friends, an upright, courageous, conscientious man; one to be trusted to the uttermost. It is as a great scientific physician that we must think of William Gordon. He worked at science at Cambridge for a year before entering the University. It was a time of immense scientific enthusiasm: the eagerness of that band of scientists whom Sir Michael Foster had

gathered round him when he founded the Cambridge scientific school was at its highest pitch; men like Sherrington, Rolleston, Bateson, Shipley, Adami, Henry Head, and Threlfall were of his time, and he was a member of the University Natural Science Club. At Trinity College, and later at University College Hospital, he and Michael Foster were great friends, and so Gordon came very directly under his influence; Langley had recently obtained his fellowship at Trinity, and from him he must have derived still further inspiration. The degree he took in the time of such a scientific galaxy speaks for itself.

Gordon came to Exeter in 1890, and, there being a vacancy for a physician on the hospital staff, he was elected to it. Thus at the early age of 27 he obtained the care of one-third (shortly to become one-half) of the medical beds in a hospital of over 200 beds. As the physicians also had charge of out-patients, he was provided with a large clinical experience at once. Here again his scientific enthusiasm and training were at once apparent. He spent a vast amount of time in the most accurate observation and careful recording of his patients' symptoms. His industry was immense, and the whole of his records were carefully tabulated and scientifically collated. No mean pianist, he had a most accurate ear for music, and it was this that enabled him to obtain the great results which he achieved in percussion. It was this also that led to his accurate observations on the changes in the heart dullness in varying postures; he could detect early lung changes that were lost to others. As a surgeon I am unfit to assess his medical achievements, but we frequently met in doubtful and anxious cases, and I never failed to be impressed by the scrupulous care of his methods and by the accuracy of his conclusions. He was invaluable to me as a medical consultant. His scientific methods led to diagnoses by exclusion that were almost uncanny. I remember a case in which he astonished everyone by diagnosing early spinal caries; there were no physical signs and merely some vague nerve symptoms, but he said "it couldn't be anything *else*." He was justified some months later. Outside his professional work he was a great reader of history, and to it he applied his scientific methods. With infinite pains he drew up parallel records of contemporary happenings throughout the world in successive centuries; his highly retentive memory enabled him to keep these synopses in mind, so that when anyone started him on the subject he revealed a wealth of historical information that was truly amazing. It may be recalled that early in 1927 he read a paper before a meeting of the Devon and Exeter Medico-Chirurgical Society reviewing the medical history of twenty-five centuries; this paper was subsequently printed privately, and was welcomed as a most valuable and interesting summary of medical progress by "periods."

I wondered at first at his coming to Exeter; it hardly seemed a big enough sphere for his scholarly attainments, and some time after his arrival I inquired his reasons. He told me of his extremely keen interest in medicine; that the opportunity of getting immediate clinical work attracted him and was not one to be lost; and that if he only succeeded in laying firmly one brick in the edifice of medical knowledge he would have his reward. Who shall say that he has not so laid—well and truly—and that his life's purpose has not been fully realized? There was no guessing about his methods; his conclusions were all the result of most careful observation. For myself, I have lost the last intimate of my own standing, and it is with a sad heart that I write the word *Vale*.

Dr. F. W. Burton-Fanning (Norwich) writes:

As an old friend of Dr. William Gordon, our friendship going back to student days at Cambridge and at University College Hospital, I welcome an opportunity to send a few *lines of appreciation*. As a consultant and in the wards of the Royal Devon and Exeter Hospital his kindness of heart, his sterling character, and his keen intellect soon won him recognition. Thirty years ago Dr. Gordon was convinced that strong rain-bearing winds had an influence on the prevalence of pulmonary tuberculosis, and in 1910 he published his work on the subject, which represented an exhaustive and laborious inquiry into phthisis mortality statistics and into the meteorological conditions of Devonshire. He had gone so deeply into his thesis that he was fully prepared with vigorous answers to his critics, and his name will always be associated with his particular views on this question. To the last his industry and mental activity were in evidence. In addition to many original contributions to clinical medicine, his fertile brain produced a volume of poems written after the war. A remarkable man has passed, and his friends will remember his warm-heartedness and his many-sided activities.

[The photograph reproduced is by Heath and Benelucc, Exeter.]

We regret to record the death, in his sixty-seventh year, of Dr. Horron Davies, which took place on September 1st at his home in Leicester. Horron Davies received his medical education at Glasgow University, qualifying L.R.C.P.Ed. and L.M. in 1882, and M.R.C.S.Eng. in 1883. Later he graduated M.D.Brux., with honours, in 1886. Having held appointments as house-surgeon to the Glasgow Royal Infirmary, and for three years as resident medical officer to the Denbighshire Infirmary, he proceeded to build up a general practice in Leicester, where, by his professional skill and friendly personality, he soon made himself popular among all sections of the community. A man with strong political interests and prominent in the Conservative party, Horron Davies closely identified himself with the public life of Leicester, becoming a member of the city council in 1889 and a justice of the peace in 1903. In association with the late Sir John Rolleston he was responsible for the creation of the Leicester Poor Boys and Girls' Summer Camp, and in many other ways was active in social, political, and philanthropic work. Davies was a keen member of the British Medical Association, and vice-president of the Midland Branch; when, in 1905, the British Medical Association held its annual meeting in Leicester, he took a prominent part in the work of organization. In the same year he was asked to become mayor of Leicester, an honour which he reluctantly found himself unable to accept. During the great war he was major in the R.A.M.C., and served at the base hospital, Leicester. Horron Davies contributed a number of papers to the medical journals, among them "Gangrene of distal parts following erysipelas" (*British Medical Journal*, 1892); "The practical working of the Leicester system" (*Lancet*, 1893); "Reinsertion of teeth, with cases" (*Quarterly Medical Journal*, 1898). He is survived by a widow and one son.

Dr. Walter Anson Smith of Shelburne Falls, Massachusetts, news of whose death, at the age of 72, has reached this country, graduated M.D. in the University of Vermont in 1882. After practising in several towns he settled at Springfield in 1894, where he continued his practice until 1922. He was one of the founders of the Mercy Hospital, which he served as a member of the medical staff, and subsequently as consultant, until ten years ago. He also took a prominent part in the foundation of the Springfield Academy of Medicine, of which he was at one time president. During a period he spent in England in post-graduate study at Birmingham, under the late Lawson Tait, he joined the British Medical Association and retained his membership until his death. In 1905 he was appointed surgeon, with the rank of lieutenant-colonel, in the First Brigade of the Massachusetts Volunteer Militia, and in October, 1907, when the militia came under national control, he became a major in the medical department. He is survived by a widow and one son.

The death took place, on September 28th, in a nursing home at Aberdeen, of Dr. Peter Mitchell, who for many years had been a well-known practitioner in that city. Dr. Mitchell was born in 1864 at Inverarn, Banffshire, and graduated M.B., C.M. at Aberdeen in 1894; he proceeded M.D. four years later. After practising for a short time at Newtonhill, Kincardineshire, he took up work in the East End of Aberdeen, where he conducted a large practice for some thirty years. Having joined the 5th Volunteer Battalion Gordon Highlanders as a surgeon lieutenant in 1898, he was afterwards transferred to the

Aberdeen Company of the Royal Army Medical Corps (Volunteers). On mobilization at the outbreak of the war he was placed in charge of the local hospital; in 1916 he was appointed to the command of the 45rd General Hospital at Salonika, where he remained till he was demobilized in 1918 with the rank of lieutenant-colonel. He had been mentioned in dispatches, and in 1918 received the Territorial Decoration. Dr. Mitchell worked in partnership with a brother; another brother, Sir William Mitchell, was *Vice-Chancellor of the University of Adelaide*, and was knighted by the King in 1926 for services to the Commonwealth of Australia. Dr. Peter Mitchell is survived by a widow and a family, including three daughters, who are all graduates in medicine of Aberdeen University, and a son.

Dr. GEORGE GEDDES of Heywood, Lancs, *died on October 1st, after an illness of only about half an hour's duration*, at the age of 61. Dr. Geddes graduated M.B., C.M.Aberd. in 1892, and proceeded M.D. in 1903. He settled in general practice in Heywood about thirty years ago, and held several public appointments, including those of medical officer for Heywood district of the Bury Poor Law Union and medical officer to the post office. He took great interest in the public life of the district; in 1923 he entered the Heywood town council and was vice-chairman of the education committee. In 1926 he was made a justice of the peace, and he took a very active part in the local branch of the League of Nations Union. In religion he was a member of the United Methodist Church and was the circuit steward for the Heywood circuit. He was a loyal member of the British Medical Association, and had served in the Rochdale Division as chairman from 1913 to 1918, vice-chairman in 1912, and as a member of the executive committee. He was keenly interested in the question of puerperal sepsis, and was the author of a monograph on the subject. In 1924 he was awarded the Nicholls Prize by the Royal Society of Medicine for his work on puerperal septicaemia. His funeral on October 3rd, at Heywood, was attended by a large gathering of his medical and municipal colleagues and patients.

The Services.

DEATHS IN THE SERVICES.

Surgeon Captain Richard Miller, R.N. (ret.), died after an operation in the Cottage Hospital at Fleet, Hants, on September 12th, aged 67. He was educated at Trinity College, Dublin, where he graduated as M.B. and B.Ch. in 1833. After filling the posts of assistant medical officer and deputy superintendent of Bethlem Royal Hospital, and of temporary medical superintendent of the East Riding Asylum, Yorks, he entered the navy as surgeon in 1887, attained the rank of fleet surgeon on February 28th, 1903, and retired on August 26th, 1917, with an honorary step as surgeon captain. After retirement he went into practice at Stock, Essex, where he was medical officer and public vaccinator of the 7th Division of the Chelmsford Union and certifying factory surgeon, retiring from practice last year. He received the bronze medal of the Royal Humane Society on February 28th, 1889, when serving as surgeon on H.M.S. *Iron Duke* at Gibraltar, for jumping overboard, fully dressed, to the assistance of Corporal Hill, R.M.L.I., and getting him safely on board again, while an easterly gale was blowing and a heavy sea running. In December, 1911, he was appointed to the charge of the Naval Mental Hospital at Great Yarmouth, and served there for five years, till July, 1916, when he was appointed senior medical officer of the battle-cruiser H.M.S. *Princess Royal*, receiving the medals granted for service in the recent great war.

Lieut.-Colonel Jerome William Morgan, R.A.M.C. (ret.), died at Seend, Wilts, on August 26th, aged 85. He was born on June 27th, 1844, and was educated in Dublin, where he took the L.R.C.S.I. in 1865 and the L.K.Q.C.P. in the following year. Entering the army as assistant surgeon on April 1st, 1867, he served in the 6th Foot, now the Royal Warwickshire Regiment, became surgeon major after twelve years' service, and retired, with an honorary step as brigade surgeon, on August 31st, 1887. He served with the 6th Foot in the Hazara campaign on the north-west frontier of India in 1868, receiving the medal with a clasp; and in the Sudan campaign in 1884, receiving the Egyptian medal and the Khedive's bronze star. He also received the thanks of the Indian Government for his services during a cholera epidemic at Peshawar in 1872.

Lieut.-Colonel James John Conway Donnati, R.A.M.C. (ret.), *died at Eastbourne on September 20th, aged 71. He was born* at Lisbon on June 18th, 1858, educated at King's College Hospital, and took the M.R.C.S. and L.R.C.P.Ed. in 1882. Entering the army as surgeon on February 2nd, 1884, he became lieutenant-colonel after twenty years' service, and retired on May 7th, 1913, rejoining for service in the recent war of 1914-18. *He served in the Nile* campaign in the Sudan in 1884-85, receiving the Egyptian medal with a clasp, and the Khedive's bronze star; also in the Sudan in 1889, when he was present at the action at Toski, and received another clasp.

Major Willis Clarence Connell, R.A.M.C., died in the British *Military Hospital at Delhi* on August 12th. He was educated at Toronto University, where he graduated as M.B. in 1916, subsequently becoming M.C.P.S.Ontario in 1919. He joined the R.A.M.C. as a temporary lieutenant on July 21st, 1916, became temporary captain, and, after a year's service, got a permanent commission as captain on January 24th, 1920, becoming major last year. He served in the war of 1914-18. He recently held the appointments of staff surgeon, Mhow, and of midwifery and gynaecology specialist of the Central Provinces District, India.

Major William Henry Forsyth, D.S.O., R.A.M.C., died at Bexley, Kent, on September 17th, aged 47. He was the third son of the late Charles Forsyth, J.P., of Northside, Berwick-on-Tweed, and was educated at Edinburgh University, where he graduated as M.B. and Ch.B. in 1904, subsequently taking the D.T.M. and H. in 1910. Entering the R.A.M.C. as lieutenant on July 30th, 1906, he became major after twelve years' service. He served throughout the war of 1914-18, was twice mentioned in dispatches—in the *London Gazette* of May 20th, 1917, and December 30th, 1918—and received the D.S.O.

Universities and Colleges.

UNIVERSITY OF LONDON.

AT the meeting of Convocation on October 8th Earl Beauchamp was elected to the vacancy in the Chancellorship caused by the death of the Earl of Rosebery.

At the September matriculation examination there were 78 successful candidates in the first division and 437 in the second division; in addition, 27 obtained the supplementary certificate for Latin.

LONDON HOSPITAL MEDICAL COLLEGE.

The following entrance scholarships have been awarded:—Scholarships in Science, £100 and £50: H. Caplin and R. Solly, equal; scholarships divided. Scholarship in Science open to students of Epsom College: J. N. Morrison. Scholarships open to students of the Universities of Oxford and Cambridge: (1) Price Scholarship in Anatomy and Physiology, £100: R. A. Jones and J. M. Vaizey, equal; scholarship divided. (2) "Freedom" Scholarship in Pathology, £100: J. F. Brock.

UNIVERSITY COLLEGE.

A public lecture on medicine in the days of Shakespeare will be given by Dr. Herbert R. Spencer at University College on November 25th at 2 p.m.

UNIVERSITY OF BIRMINGHAM.

Faculty of Medicine.

THE following prizes were presented to the successful candidates by Sir E. Farquhar Buzzard, Bt., K.C.V.O., M.D., F.R.C.P., on October 1st:

Peter Thompson Prize (for Anatomy) and Foyle Prize (awarded in 1928-29 for Physiology), P. J. Stoy; Arthur Foxwell Gold Medal (for Clinical Medicine — Final M.B., Ch.B. Examination) and Ingleby Prize for Midwifery and Diseases of Women (value £10 Final M.B., Ch.B. [illegible] Smallwood; Sampson Gamgee Gold Medal (Ch.B. Examination), C. St.Johnston E. G. Abdel-Malek. Prizes awarded: Bond: Senior Medical Prize, Senior Prize (Gold Medals), W. C. Smallwood; Junior Surgical Prize (Silver Medal), G. R. Bashford.

UNIVERSITY OF LIVERPOOL.

THE following candidates have been approved at the examination indicated:

D.P.H.—J. L. Clegg, R. L. Corlett, R. W. Eldridge, A. B. Follows, R. S. Jarvis, J. C. McVittie, R. J. Ormsby, D. E. P. Pritchard, D. Regan, F. C. Speechly.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS, IRELAND.

THE following candidates have been approved at the examination indicated:

D.P.H.—E. J. Daly, A. B. Monks, T. V. C. Nolan, J. H. Owen-Flood.

Medical News.

Four lectures on "How England learned to control disease" will be given by Sir George Newman, K.C.B., at Gresham College, Basinghall Street, E.C.2, on October 15th, 16th, 17th, and 18th at 6 p.m. Admission to the lectures is free.

The Long Fox Memorial Lecture will be delivered in the Physiological Lecture Theatre of the University of Bristol by Mr. A. Rendle Short, M.D., F.R.C.S., on Tuesday, October 22nd, at 8.30 p.m.; the subject will be ten years' progress in surgical treatment.

Sir Leonard Rogers will deliver the inaugural address to the Abernethian Society of St. Bartholomew's Hospital on the evening of Thursday, October 24th. His subject is "Climate and disease: forecasting epidemics in connexion with small-pox, cholera, and plague."

The annual dinner of past and present students of University College Hospital will be held at the Hotel Cecil on Friday, October 25th, at 7 p.m. Tickets may be obtained on application to the honorary secretaries at the Medical School.

The Royal Microscopical Society will hold its annual pond life and general microscopical exhibition in the lecture hall and library at 20, Hanover Square, W., on Wednesday, October 16th, at 7.30 p.m.

The annual Corporate Communion of the Guild of St. Luke will be celebrated at Grosvenor Chapel, South Audley Street, W.1, on *St. Luke's Day, Friday, October 18th*, at 8.15 a.m. The annual general chapter will be held the same afternoon, at 5 o'clock, at King's College, Strand. The annual service will be held in Westminster Abbey on Sunday, October 20th, at 6.30 p.m., when the Bishop of Bradford will preach; members are invited to wear academic dress and to robe in the Jerusalem Chamber, after notifying in advance the secretary of the Guild, King's College, Strand.

The general meeting of the Guild of St. Luke, St. Cosmos, and St. Damian will be held in the Westminster Cathedral Hall, Archbishop's House, on *Sunday, October 20th, immediately* after High Mass in the Cathedral, which will be celebrated at 10.30 a.m. Annual reports will be received, and the officers and council will be elected.

The opening lecture of the series on common complaints, arranged by the Fellowship of Medicine, will be delivered at the Medical Society of London, 11, Chandos Street, Cavendish Square, W.1, on Monday, October 14th, at 5 p.m., by Dr. F. G. Chandler, whose subject will be the treatment of pulmonary tuberculosis. On the same afternoon, from 2 to 4, Dr. W. Griffith will give a clinical demonstration at St. John's Hospital for Skin Diseases (Leicester Square); on October 17th Mr. McAndrew will give a demonstration at the Samaritan Hospital for Women at 2.30 p.m. Both demonstrations, as well as the lecture, are free to medical practitioners. The series of sixteen lectures arranged for M.R.C.P. candidates will begin on October 15th, and will continue until December 6th. The lectures are given on Tuesdays and Fridays at 8.30 p.m. at the Medical Society of London. From October 14th to 26th a morning course will be held at the Hospital for Sick Children, and a course in gynaecology at the Chelsea Hospital. There will be an intensive course at the Central London Throat, Nose and Ear Hospital from October 14th to November 2nd, comprising operative and pathological classes. An intensive course in medicine, surgery, and the specialties will continue at the Metropolitan Hospital from October 21st to November 2nd. Copies of all syllabuses, information regarding the general course of work at the associated hospitals, and specimen copies of the *Post-Graduate Medical Journal* may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

The fourth of a series of dances in aid of the Royal Medical Benevolent Fund Guild will be held in the Great Hall of the British Medical Association, Tavistock Square, W.C.1, on October 31st, from 8.30 to 12.30. Tickets, price 11s. double and 6s. single, may be obtained from Miss English, 82, Brook Street, W.1; Mrs. G. A. Ewart, 25a, Norfolk Crescent, Hyde Park, W.2, and Mr. H. Ferguson, St. George's Hospital, S.W. Application for bridge tables should be addressed to Mrs. Harold Barwell, 39, Queen Anne Street, W.1.

The international congress of cancer research will be held at Barcelona from October 28th to 30th. The international congress of microbiology, which was to have taken place this month, has been postponed until next July.

Under the auspices of the National Council for Mental Hygiene, in association with the joint committee of the National Council for Mental Hygiene and the Tavistock Square Clinic, a conference on mental health will be held at the Central Hall, Westminster, from October 30th to November 2nd. The subjects for general discussion will be: sex education, the personal equation in industry, child and parent, and delinquency; in addition, magistrates and probation officers will hold a group discussion on the working of the juvenile courts, public health nurses and social workers on the relation of their work to the mental health of the community, and parents and teachers on the problem child at home and in school. The cost of an inclusive ticket (to cover the whole conference) is 7s. 6d., for a single session 2s., and for a single group discussion 1s. Further particulars may be obtained from the secretary, National Council for Mental Hygiene, 78, Chandos House, Palmer Street, S.W.1.

The King has granted permission to Sir Charles H. Bedford, D.C.L., LL.D., M.D., D.Sc., Lieut.-Colonel I.M.S. (retired), to accept and wear the Insignia of Knight Grand Cross of the Order of Civil Merit of Spain, bestowed upon him by H.M. the King of Spain for specially distinguished services.

The offertory at the Liverpool annual medical service in the Cathedral on October 13th, at 3 p.m., will be in aid of the Royal Medical Benevolent Fund. The preacher will be the Bishop of Derby, and the Lord Mayor and Lady Mayoress will be present. Medical practitioners and their friends are cordially invited to attend. Tickets may be obtained from Dr. R. Kennon, 28, Rodney Street, Liverpool.

On October 6th the staff of the Public Health Office of the Blackpool Corporation presented Dr. E. W. Rees-Jones, medical officer of health for Blackpool, with a gold hunter watch suitably inscribed, in recognition of the services he had rendered during his twenty-one years of office. On the same day Dr. Rees-Jones was the recipient of a presentation from the nursing staff at the sanatorium, Talbot Road.

The London School of Dermatology commenced its winter session last week with a lecture on "The rise and progress of dermatology," delivered by Dr. James H. Stowers at St. John's Hospital for Diseases of the Skin, Leicester Square. Lectures will be given every Tuesday and Thursday throughout the winter months.

At a meeting of the Society of Public Analysts on October 2nd H. E. Cox, M.Sc., Ph.D., read a paper on chemical tests in relation to fur dermatitis. He stated that paraphenylene diamine, the intermediate most frequently used in the process of dyeing furs, was also the most toxic, and expressed the view that the so-called Bandrowski's base was not a fast final product; it was, he said, easily reduced, re-forming p-phenylenediamine, and so might be an indirect cause of irritation. In the *British Medical Journal* of June 8th (p. 1048), attention was drawn to the risk of severe dermatitis attending the use of paraphenylenediamine as a hair dye.

The forty-fourth annual meeting of the Caledonian Medical Society was held at the residence of the medical superintendent (Dr. David Blair), County Mental Hospital, Prestwich, Manchester, on October 4th, under the presidency of Dr. D. Sage Sutherland. The president took as the subject of his address the journey of Johnson and Boswell through Scotland *en route* to the Hebrides in 1773, referring especially to that part of it which lay through the county of Inverness. A number of books of interest in connexion with the subject were on view. A vote of thanks was proposed by Dr. W. E. Henderson (Windermere). The annual dinner took place the same evening at the Queen's Hotel, Manchester, with Dr. Sutherland in the chair. The speakers included Judge Leigh, Mr. A. H. Burgess (President of the British Medical Association), Mr. Harry Platt, Dr. Cameron Blair, and Dr. Corsar Sturrock. On the next morning visits were paid to places of interest in the city, such as the Ryland Library and Chetham's Hospital, and in the afternoon members enjoyed a drive through Knutsford and the Gaskell country to Alderley Edge, where they were hospitably entertained by Professor and Mrs. A. Donald.

Dr. G. Stuart, Colonial Medical Services, has been awarded the North Persian Forces Memorial Medal for 1928 for his paper on "The serological diagnosis of the enterica by the method of qualitative receptor analysis," written in conjunction with Dr. K. S. Krikorian, and published in the *Journal of Hygiene*, November 26th, 1928, p. 105. This medal is awarded annually for the best paper on tropical medicine or hygiene published in any journal during the preceding twelve months by a medical officer, of under twelve years' service, of the Royal Navy, Royal Army Medical Corps, Royal Air Force, Indian Medical Service, or of the Colonial Medical Service.

Count Wladislaus Semsey, one of the richest magnates in Hungary, has presented 300 milligrams of radium to the Hungarian Minister of Public Health for the treatment of cancer.

Dr. Louis Davraigne, head of the maternity department of the Hôpital Laribaisière, Paris, has been nominated the successor of Dr. Jules Comby in the presidency of the Pierre Budin Foundation of Puericulture.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR of the *British Medical Journal, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocern Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TREATMENT OF METRORRHAGIA.

DR. [illegible] in reply to an inquiry as to [illegible] ublished an article in the *Pr* [illegible] current in treatment of uterine haemorrhage," with details of the method of copper ionization adopted in several cases. In one of these every form of treatment had been tried, and hysterectomy was being considered by the gynaecologist who sent the patient to me as a last resort. *The late Dr. Sloan, in his book Electro-therapy in Gynaecology*, describes this method, and much has also been written on the subject by Dr. Zimmern of Paris.

TREATMENT OF SEVERE HEADACHE WITHOUT PHYSICAL SIGNS.

DR. I. SACKS (Winburg, South Africa), in reply to the inquiry of "M.B." under the above heading (August 17th, p. 330), recommends the administration, every two hours, of liquor sedans (Parke, Davis and Co.) in doses of one drachm in a wineglassful of warm water, with or without the addition of bromide.

INCOME TAX.

Cash Basis and Debts.

"J. M. J." has been requested by the local inspector of taxes to state the gross amount of fees earned in the year, and to explain how bad debts are dealt with. The gross income of the practice has been returned for assessment on the cash basis.

*** The basis which is legally correct is the value of the gross bookings of the year—that is, the nominal amount less a reasonable and carefully considered allowance for bad and doubtful debts. Where the practice is not materially increasing or decreasing from year to year, the amount of cash received is a fairly accurate indication of the value of the bookings, and in such cases the revenue authorities usually accept the cash basis, especially in such a case as this, where the loss in bad debts is heavy and the amount difficult to estimate. If "J. M. J." puts these points to the inspector it may very well be that he will agree to the cash basis being continued.

Cash Basis for Return.

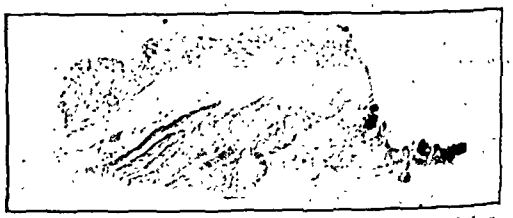
"W. H. P." was formerly in practice with his father, but the latter died three years ago. The accounts have always been prepared on a cash basis, but the inspector of taxes is now asking for a "certificate that the receipts represent gross earnings—cash and credit."

*** The inspector of taxes has no legal right to demand this information, but it is a question relevant to the amount to be assessed, and the Commissioners who have that right would probably insist on the information being given, if necessary. Assuming that the gross income of the practice has been reasonably constant during the past three years, the cash basis would yield approximately the same result as the basis of taking the *value* of the year's bookings, and if that assumption is justified we suggest that our correspondent should state the fact in his reply and point out in that case the gross receipts as returned for assessment, though calculated according to the amount of cash received in any particular year, do fairly "represent the gross earnings—cash and credit." If the nominal amount of the outstanding debts at the end of each year can be calculated without undue trouble, it might be worth while giving those figures as proof that the real income of the practice has not been rising, and therefore that the cash basis is not unfair to the Revenue.

LETTERS, NOTES, ETC.

CHRONIC GASTRIC ULCER IN A SEA-LION.

MR. DOUGLAS ROBB, M.D., F.R.C.S., assistant surgeon, Auckland (N.Z.) Hospital, sends the following interesting note. An elderly male sea-lion (*Arctocephalus hookeri*) in the Auckland Municipal Zoo was unexpectedly found dead one morning. The animal had been taking its food (mainly fish) well, and seemed in good condition, though of late unwilling to take its usual exercise. There had been a period, some months previously, when it had become very thin, though latterly its appearance had returned to



omental tissue, in which the eroded artery was found.

normal. Post-mortem examination showed the cause of death to be a large haemorrhage into the stomach from a chronic ulcer. The ulcer was 2 in. in diameter, and situated on the posterior surface of the stomach, at the junction of the middle and distal thirds, near the lesser curvature. It resembled in all respects the chronic peptic ulcer of man, having eroded cleanly through mucosa, submucosa, and muscle, and having for its base peritoneal and omental tissues in which an artery about 1 mm. in diameter had been eroded. There was no adhesion of the base to pancreas.

"CONDITIONING" OF BEEF.

THE Food Investigation Board of the Department of Scientific and Industrial Research has issued a report by T. Moran and E. C. Smith, entitled "Post-mortem changes in animal tissues—the conditioning and ripening of beef." The authors, after a protracted investigation, concluded that hanging, or, as it is sometimes called, "conditioning," has a favourable effect on the palatability and tenderness of meat, especially of the coarser cuts. They found that beef could be stored for seventeen days at a temperature ranging from 32° to 41° F. and still reach the consumer essentially unaltered, save for an improvement in its palatability. From their observations of the post-mortem changes in animal tissues they are convinced that conditioning of beef may be carried out at central abattoirs, and they propose a procedure whereby such conditioning may be secured efficiently. The report may be obtained from H.M. Stationery Office, price 2s. net.

LECTURERS ON HYGIENE.

MRS. C. NEVILLE ROLFE, secretary-general, British Social Hygiene Council (Carteret House, Carteret Street, S.W.1), writes: The British Social Hygiene Council are undertaking a considerable amount of campaign work during the coming winter, and would be glad to receive applications from medical men and women willing to give single lectures in London or to undertake short campaigns in the provinces. The fee for a single lecture in London is 1 guinea.

AN APPEAL.

THE colleagues of the late Dr. W. E. Powell are trying to raise a fund to help his widow and family of young children; Dr. Powell died at an early age, before he had time to make the necessary provision himself. The Brighton and Sussex Medico-Chirurgical Society and the Brighton Division of the British Medical Association have jointly launched an appeal, and [illegible] rect to J. G. Ellis, [illegible] Street, Brighton, surer to the fund.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 49, 50, 51, 52, 53, 56, 57, 58, and 59 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 171.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

305. Apical Tuberculosis.

Investigations during the last five years have clearly demonstrated that, the more carefully early cases of pulmonary tuberculosis are studied, the larger will be the proportion found of lesions originating below the clavicle. M. Fishberg and A. Shamaskin (*Journ. Amer. Med. Assoc.*, July 13th, 1929, p. 108) quote from a study by Fowler of the pathological anatomy of the tuberculous lung that the earliest lesions are, as a rule, located below the clavicle, and that, with the progress of the disease, they extend upwards to the apices and downwards to the lower lobes. Braeuning, Lydtin, and many other authorities have stated that the first lesion seen on the radiogram in active and progressive tuberculosis is in more than 90 per cent. of cases situated below the clavicle, most commonly towards the axillary region, while the apices remain free. With the appearance of these lesions, the symptoms of active phthisis are more or less pronounced. When the physical signs clearly show an apical lesion the process has lasted for some time, and extended from the infraclavicular localization to the apex. The present authors have examined the radiograms in 1,000 cases of tuberculosis with the clinical history and course of the disease in each instance. In 160 cases the *x*-ray signs were quite clear. In 107 the earliest localization of lesions was infraclavicular, and in 60 supraclavicular. In 31.7 per cent. with apical lesions, the patients survived for ten or more years after the first symptoms of the disease, and, despite extensive involvement of the apices, felt fairly well. Fishberg and Shamaskin conclude that pulmonary tuberculosis limited to the apex usually has a benign course, and in many cases there is no need for prolonged treatment. Though the physical signs and radiographical changes may persist for many years, the patient survives and may be able to work, even though suffering at irregular intervals from exacerbations, which are usually mild and abate. The presence of the initial lesion below the clavicle is of greater clinical significance, and in most cases demands immediate attention. Such cases almost always occur in persons under the age of 35. Patients with apical lesions generally have less marked constitutional symptoms, especially fever. Haemoptysis occurs in both groups, but those patients with lesions below the clavicle are more apt to bleed copiously. Open tuberculosis is found in only 15 per cent. of apical, as against 66.4 per cent. of infraclavicular lesions; the former, therefore, are not such a menace as the latter.

305. Anaemia due to Gastric Deficiencies

M. Hochrein (*Münch. med. Woch.*, August 9th, 1929, p. 1327) describes two cases of anaemia occurring in patients on whom seven and eight years previously gastrectomy had been performed. In one case the blood picture suggested pernicious anaemia, in the other the picture was that of secondary anaemia. In both patients the anaemia was relieved after treatment with liver, the haemoglobin rising from 54 to 70 per cent. and from 43 to 85 per cent. respectively; the red cell counts rose from 1,560,000 to 4,800,000 and from 3,420,000 to 4,460,000 per cubic millimetre respectively. The common factor in these cases was a functional deficiency of the stomach. The author refers to achylia gastrica as being a constant symptom of pernicious anaemia. He concludes that under certain conditions a similar noxious agent can evoke in different individuals quite different reactions, so that various blood pictures may result from similar causes.

307. Iodide and Bromide Rashes.

W. H. Goeckerman (*Minnesota Med.*, July, 1929, p. 408) reports twelve cases of uncommon eruptions following the administration of iodine and bromine. The majority of the patients were women who had been taking the drug, often without medical supervision or advice. The author shows by photographs the varied nature and distribution of the lesions, and points out the impossibility of distinguishing the results of the two drugs. The lesion usually begins with a pustule, but later part of it is commonly warty, the remainder being a crust of inspissated serum and pus with secondary scarring. There is no characteristic distribution, but the legs are most often affected. Final diagnosis can only be made by collateral evidence. Recovery of the drugs from the urine is not always possible, and rarely from the scales and crusts. If the diagnosis cannot be finally settled a small provocative dose of the drug concerned will produce an exacerbation of the symptoms with local reaction in the lesions. Most of the patients in the author's series had taken the drugs for months or years before these unusual lesions appeared. He thinks that severe cases are best treated in bed with cathartics and increased intake of fluids. Mildly antiseptic wet dressings such as those utilizing potassium permanganate or boric acid, are useful. As the fungating lesions dry the crusts should be removed. In painful cases one or two quarter to half skin doses of unfiltered *x* rays have been helpful, and have aided the drying of the lesion. Some cases closely resemble malignant disease in the great proliferation of the epidermal epithelium.

303. Cardiac and Pulmonary Efficiency Tests.

A. Thouvenel (*Paris Méd.*, August 3rd, 1929, p. 123) has recorded the pulse and respiration rate in 80 children of 9 to 14 years of age, before and after exercise, which consisted of the elevation to the horizontal of the lower limbs, right and left alternately, fifty times, at the rate of ten movements in five seconds. The increase in the pulse rate ranged from 8 to 64 per minute, with an average of 33. The return to normal took one minute in 17, two minutes in 14, and two to five minutes in 16 cases. A repetition of the experiment with the same children, after a rest, the same day and on succeeding days, gave, except on one occasion, results that varied from the previous ones by 2 to 34 pulsations per minute. The increase in the respiration rate varied from four to eighteen per minute, an average of eleven. Here, too, it was found that the results obtained were not constant, a repetition of the experiment giving results that varied from the previous ones by two to four respirations per minute. There was no relationship between the increase in the pulse rate and that of the respiration.

309. Hemiplegia of Cardiac Origin.

E. Nedelec (*Thèse de Paris*, 1929, No. 157), who records six cases, in patients aged from 28 to 64, states that of the nervous manifestations encountered in cardiac disease, hemiplegia of various forms is the most frequent. The majority of the cases of hemiplegia are permanent, but a certain number are transient. This transient form of hemiplegia may be met with in all cardiac affections and at all ages, but is most frequent in cardiac disease of long standing. Owing to its organic origin it cannot be distinguished from permanent hemiplegia, except by its evolution. The pathogenesis is not yet clearly understood, the condition being variously attributed to cerebral embolism, vascular spasm, or chronic arteritis. The prognosis is difficult to establish owing to the absence of distinctive clinical signs, but the condition always indicates a serious involvement of the cardio-vascular system.

Surgery.

310. Subphrenic Abscess.

T. H. Russell (*Annals of Surgery*, August, 1929, p. 238) describes a subphrenic abscess as a localized inflammatory process between the domed surface of the liver below and the diaphragm above, the liver and its coronary ligament dividing this area into an anterior and posterior space. The upper part of the subphrenic space is divided into a large right and small left space by the suspensory or falciform ligament, and the liver also divides this space into a supra-hepatic and infrahepatic space. The majority of abscesses occur in the right side, although perforation of the stomach, or pancreatic, splenic, or renal infections, may be complicated by a subphrenic abscess on the left side. The micro-organism most frequently found is the colon bacillus, although the streptococcus, pneumococcus, *B. pyocyaneus*, and rarely the tubercle bacillus may be found. Out of 24 cases recorded, 6 complicated appendicitis and 6 gall-bladder disease, 4 were associated with pneumonia, empyema, or pleurisy, 2 cases followed perforated duodenal ulcers, 2 developed after trauma to the upper abdomen, 1 case was due to exposure, and 1 to abscess formation with actinomycosis of the right pleura and subphrenic space. Subdiaphragmatic abscess may develop rapidly after abdominal infection, but sometimes months, or even a year, may elapse. The symptoms resemble those found in diseases of the lower part of the thorax, with pain in the epigastrium, the right or left hypochondrium, or the lumbar region, and frequently referred to the end of the twelfth rib. The pain is sharp and pleuritic in character,

and in an abscess on the right side a perihepatitis is usually present with rales in the lower chest. Paralysis of the *diaphragm with depression of the liver may* be an early symptom if the abscess is infraperitoneal; the liver does not move up and down freely with respiration, and there may be jaundice or the so-called purulent complexion. When a subdiaphragmatic abscess is well developed the prognosis is grave, the mortality rate being from 20 to 50 per cent. The use of an aspirating needle in making a diagnosis is to be condemned, and should be replaced by an *x*-ray examination. An exploratory abdominal incision in the epigastrium or through the right or left upper rectus muscle gives valuable information as to the best methods of opening and draining the abscess. If the abscess when located is to be drained through the abdomen the pus can be removed without spilling by means of a suction tube, as used by a laryngologist; a counter-incision is then made between the ribs in the lateral or posterior wall of the upper abdomen and through drainage instituted. It is sometimes possible to incise along the costal border down to the peritoneum, which is then stripped, the abscess being entered extraperitoneally. Some cases can be drained through an incision in the ninth or tenth intercostal space if pus is present in the posterior space, a double rubber tube being introduced into the abscess cavity. Early recognition and proper surgical treatment should reduce the present high mortality rate.

311. Suprarenal Virilism.

A. D. FORDYCE and W. H. EVANS (*Quart. Journ. Med.*, July, 1929, p. 557) report two cases of suprarenal virilism with cortical hypernephroma. The first, a boy aged 2 years and 3 months, the son of normal parents, weighed 9¾ lb. at birth, and 3 st. when 8 months old, but towards the end of the second year he lost weight, and at the time of examination he weighed 2 st. 10 lb., and was 2 ft. 10 in. in height. He was shy and of a most rubicund complexion with vivid red hair; his body was covered with downy hairs, and there were coarse hairs on the chin, upper lip, cheeks, breast, axillae, and pubis. The spleen was palpable and both testicles were large and in the scrotum, and the penis was as large as that of an adult. A left cortical hypernephroma was diagnosed; it was found at operation in the position of the left suprarenal capsule and not attached to the kidney. The boy died a few hours after its removal. Pathologically the main tumour was one of the suprarenal cortex, and two metastases were discovered in the liver and brain. No chromaffin tissue could be recognized and the testes were in an undeveloped state. The second patient, a girl aged 2, of normal parents, had red hair and a vivid complexion. The labia and clitoris were much enlarged and there was a profuse growth of coarse hairs, and downy hairs on the upper lip. A large tumour was removed, after which the abnormalities gradually disappeared. The extreme redness of the hair was a striking feature in both cases, and in the case of the boy the larynx presented the characteristic deformity found in congenital laryngeal stridor — namely, exaggeration of the normal infantile peculiarities resulting in narrowing in the transverse diameter of the upper aperture.

312. Pharyngeal Diverticulum.

A. NEWTON (*Journ. Coll. Surg. Australasia*, July, 1929, p. 3) discusses the etiology, morbid anatomy, symptoms, and treatment of pulsion diverticulum of the pharynx. These pouches emerge in the posterior mid-line between the oblique and transverse fibres of the crico-pharyngeus muscle. The cause is unknown, but the pouching may be due to congenital weakness of the pharyngeal wall, to abnormal propulsive and sphincteric muscular co-ordination, or to trauma from the impaction of a firm portion of food in the pharynx. Noisy deglutition is one of the earliest and most constant signs, followed by an uncomfortable sensation of pressure in the neck as the sac fills, with regurgitation of unaltered food. Wasting and malnutrition may result. *Notes are given of* successful operation upon five cases with no recurrences. Co-operation between the surgeon and the laryngologist is essential for effective treatment. Before the operation the pouch is washed out with sterile water, and intranasal ether anaesthesia is induced. After passing the oesophagoscope and emptying the sac with a suction pump to prevent the risk of pneumonia from insufflation of its contents into the lungs and to lessen the risk of contamination of the field of operation, the pouch is loosely packed with gauze and a bougie is passed. Small pouches can be invaginated into the pharynx, the neck of the pouch being surrounded with a purse-string suture, but in larger pouches the stump of the mucous lining is invaginated into the pharynx by a purse-string suture, and the tunica fibrosa is so arranged as to overlap across the weak spot in the pharyngeal wall. Although a one-stage operation is to be preferred, the operation can be performed in two stages, with ten days' interval, special care being taken to repair the weak spot at the second operation.

Therapeutics.

313. Indications for Using Acetylcholine.

J. HEITZ (*Arch. des Mal. du Cœur*, June, 1929, p. 383), in a critical review of the diagnostic and therapeutic uses of acetylcholine, recalls the fact that this derivative of choline, when injected subcutaneously, causes dilatation of the arterioles, with increase in the volume of the limbs and reduction of the blood pressure. The drug produces these effects by its action upon the nerves supplying the blood vessels, and by its direct influence upon the plain muscle of the arterioles. Acetylcholine differs pharmacologically from histamine in that the latter dilates the capillaries while constricting the arterioles. Administered in moderate doses subcutaneously, no modification of the cardiac rhythm is produced, but by retinoscopy a dilatation of the retinal vessels, lasting about ten minutes, is observed. The author describes a method by which acetylcholine can be employed in the diagnosis of arterial spasm. The latter has hitherto been investigated by noting whether or not the oscillations of a sphygmomanometer applied to the limb increase when the extremity is placed in a hot bath. These oscillations are augmented according to the degree to which the reduction of blood supply is due to spasm. It has been found that the *subcutaneous injection of 0.1 to 0.2 gram of acetylcholine* will simulate the effect of a hot bath, and cause the return or increase of oscillations which had been absent or reduced, owing to spasm of the vessels supplying the limb. These investigations have shown that even in a diseased blood vessel there is frequently superadded spasm, causing still further impairment of the blood supply. Acetylcholine has been administered therapeutically, with varying results, in several conditions. In Raynaud's disease and obliterative arteritis daily injections of 0.3 gram over periods of weeks or months have given satisfactory results, while the use of the drug in scleroderma, angina pectoris, and permanent hypertension has not been so successful. In spasms of the retinal and cerebral arteries, and in lead colic, acetylcholine frequently gives extremely good results.

314. Sodium Salicylate in Infantile Hemiplegia.

P. BARRY (*Paris Méd.*, August 17th, 1929, p. 158) reports a case of acute encephalitis, probably of infectious origin, in a little girl aged 6. There was an onset of headache associated with raised temperature, violent convulsions, involuntary passage of the urine and faeces, and vomiting, followed by complete paralysis on the right side and of the *seventh nerve on that side, temporary suppression of* urine, extreme dilatation of the left pupil, aphasia, and mental disturbance. Lumbar puncture negatived the presence of meningitis. After receiving without effect 0.5 gram of uroformine by the mouth on three successive days, an injection of 10 c.cm. of a 10 per cent. solution of sodium salicylate in glucose (1 gram of the salicylate) was given into the left arm; about three-quarters of an hour later, after an attack of profuse sweating, the symptoms began to abate. The injections were repeated daily for twenty-three days. The condition of the patient rapidly improved; she could soon walk alone, speech was slowly regained by re-education, and after three months there persisted only a weakness of the forearm, which was treated by calcium ionization, and a limited vocabulary, which at the patient's age would soon be extended. The author refers to the remarkable tolerance for glucose solution which was manifested by the delicate veins of the child.

315. Acriflavine in Undulant Fever.

A. M. HOFFMAN (*Journ. Amer. Med. Assoc.*, June 29th, 1929, p. 2169) states that the treatment of undulant fever is still empirical, and that symptomatic measures do not shorten its usual duration, which ranges from six weeks to eighteen months. Thus the economic loss involved is considerable, and any *method* that shortens this period is of *value*. The administration of vaccines, colloidal metals, and mercurochrome has met with little success. In 1927 Izar and Mastroeni found that acriflavine dyes had a markedly bactericidal action *in vitro* on *Brucella melitensis*, and they reported favourable results from the intravenous injection of acriflavine hydrochloride (0.01 gram per kilo of body weight). Three cases are now reported; the diagnosis in each was confirmed by agglutination tests. In one instance cure seemed to occur spontaneously; in the other two this was obtained by intravenous injections of acriflavine base. Serial doses of 0.1, 0.25, and 0.4 gram, and of 0.2, 0.3, and 0.4 gram, were administered to each patient respectively at intervals of two to three days. With each injection one patient had moderate though distressing reactions while the injection was being given; the slower the rate of injection, the less the distress. In each instance the duration of the disease was considerably shortened. Hoffman states that acriflavine, if injected properly, can do no harm.

Radiology.

316. Radiography of the Bladder.

M. SGALITZER (*Wien. klin. Woch.*, May 9th, 1929, p. 648) describes a radiographic method of examining the bladder which is said to be specially applicable when such conditions as haemorrhage render cystoscopy impracticable. After using various quantities of fluid and taking skiagrams in different positions, he has found the following technique the most satisfactory. He injects 50 c.cm. of an opaque fluid into the bladder. If this fails to show any irregularity in the wall, such as might be produced by a new growth, the bladder is filled with a further 50 c.cm. of solution and two skiagrams are taken, one in the antero-posterior direction and the other "axial." For the latter exposure the patient sits on the film, bending the trunk backwards and supporting himself on his arms, while the tube is so placed that the rays pass through the bladder in a cephalo-caudal direction just above the pubes. The patient may also be rotated slowly behind the *x*-ray screen, and the bladder be screened while it is being emptied. Partial filling of the bladder with 50 c.cm. best demonstrates polypoid growths which project into the lumen of the bladder; this filling defect may be obscured again when more fluid is injected, while distending the bladder more completely with 100 c.cm. reveals more readily those tumours which have infiltrated the bladder wall and only project slightly into the lumen. This method of examination not only helps in most cases to differentiate tumours from other affections of the bladder wall, but will generally show the size of the tumour and give an approximate idea of the area of bladder wall involved; it can, however, give little indication of the benign or malignant nature of the growth. Since the 15 per cent. solution of sodium bromide mixed with 1 per cent. novocain originally used was found to be somewhat irritating to an inflamed bladder, Sgalitzer uses for preference collargol or 20 per cent. iodipin. The latter is not miscible with urine, and it is therefore essential that before the injection the bladder should be completely emptied by catheter with the patient in various positions (recumbent, erect, and knee-elbow), since catheterization in the recumbent position only will not entirely empty it.

317. E. BORCH-JOHNSON (*Norsk Mag. f. Laegevid.*, September, 1929, p. 952) records four cases, in patients whose ages ranged from 25 to 56, in which severe complications followed cystoscopy with catheterization of the ureters and pyelography. Two of the patients died after showing signs of infection and uraemia, and in the others haematuria of long duration developed. While the concentration of the fluid does not seem to play any important part, the quantity of the solution injected is of great importance; in infected cases the examination ought to be performed in two or more stages. In cases with nitrogen retention, pyelography, especially when it is bilateral, is a serious procedure. Cystoscopy should always be performed with great gentleness and preferably under local anaesthesia.

318. Radiological Examination of the Uterus.

G. COTTE (*Journ. de Radiol. et d'Électrol.*, June, 1929, p. 321) maintains that radiological examination of the uterus and tubes presents no technical difficulty; lipiodol, which is usually employed for this purpose, is completely innocuous and perfectly tolerated, and involves a minimum of inconvenience. The examination should be made immediately after menstruation, as then the os is more easily permeable and the risk of [illegible] a commencing, undiagnosed [illegible] the injection a manometer is [illegible] mentally the tubes have withstood pressure of 30 to 40 c.cm. of mercury, Cotte never exceeds 20 to 25 c.cm.; in this way interstitial rupture of the tubes is prevented. If the uterus be normal 5 to 6 c.cm. of lipiodol is sufficient to inject the tubes. The sound should not be introduced beyond the isthmus, thus eliminating all risks of injury to the uterine mucosa or interruption of a pregnancy. After the photograph has been taken the plate should at once be developed to determine if the injection has been correct and sufficient; if not, a second exposure should be made, and, if necessary, one in profile. The operation, for which anaesthesia is not requisite, should be performed as quickly as possible, since the uterus, being under pressure, contracts; this sometimes causes sharp pains, which subside when the uterus is emptied. The lipiodol in the uterus drains away by the vagina; that in the tubes either empties into the uterus or passes into the peritoneum. If the latter occurs no harm ensues; this is shown to be the case by the fact that in subsequent laparotomies no inflammation or other evidence of irritation has been observed. Radiography of the uterus and tubes should be preceded by a most careful clinical examination in order to exclude unfavourable conditions. Pregnancy is an absolute contraindication, and the method should be reserved for particular cases, especially those in which later radiotherapy is anticipated. It is useful in the differential diagnosis of fibromas and tumours of the ovaries or of other sites; in certain obstinate types of dysmenorrhoea and amenorrhoea it sometimes gives valuable information. The method is of particular value in the etiological diagnosis of sterility. In order to avoid all inflammatory reaction patients should remain in bed for twenty-four hours or longer, if necessary, after the operation.

319. Radiotherapy of Breast Carcinoma.

M. PONZIO (*Med. Welt*, August 3rd, 1929, p. 1097) reports on 304 of 545 cases treated in the Turin radiological institute since 1908. They are classified as (1) operable, (2) operated on, (3) inoperable, the last including about 200 of the cases; they have all been followed up. In many instances *x*-ray therapy has been combined with radium, the dosage being varied to suit the requirements of the case. The results were on the whole favourable; in the first group definite diminution in size of the growth is found, and has been more marked after improvement of the technique; several of these patients are alive and well; early cases where operation has been followed by radiation gave better results than operation without radiation; later cases with similar treatment were favourable in that recurrence was postponed for three to five years; in still more advanced cases recurrences and metastases were delayed and limited, and life was prolonged two to five years. Ponzio remarks that in the very earliest diagnosable cases radiation alone may be tried, but in most cases an operation followed by radiation is advisable; it should be applied particularly in the clavicular, cervical, and axillary regions in the hope of destroying neoplastic elements set free by the operation and occupying the lymph channels. When glandular involvement is known or suspected, massive doses over small areas should be given; in some instances, when the glands are deeply infected, surgery should be limited to the breast itself and any easily accessible nodules, leaving the lymphatics to radiation; in very advanced cases better results are obtained by radiation alone than by partial removal surgically. Radiation actually aggravates the condition, and cannot therefore be used in cases when very widespread tumour formation is accompanied by severe cachexia, toxic absorption, and disturbance of function. The author concludes that surgery combined with radium is the treatment of election in early cases. Inoperable cases should be treated medically and with radium and *x* rays. Of the former, 65 per cent. have remained healed after four years; of the latter, in 45 per cent. life has been prolonged more than two years.

Obstetrics and Gynaecology.

320. Headache at the Menopause.

N. C. STEVENS (*New England Journ. Med.*, July 25th, 1929, p. 168) from a study of 28 cases discusses a hitherto undescribed symptom-complex occurring in women between 45 and 60 which is characterized by headache, fatigue, nervousness, subnormal temperature, dry skin, sensitiveness to cold, and a low basal metabolic rate. The majority of such patients are relieved by the administration of thyroid extract, the author's practice being, when the basal metabolic rate is definitely subnormal, to give one grain twice a day for one week and then once a day for three weeks under weekly observation. Luminal is sometimes of value, and the patient is urged to take regular daily outdoor exercise. The headache, rarely severe, is usually frontal and dull in character; it recurs two or three times a week, while vertigo is common. The results of treatment with thyroid extract were striking; only a few derived no benefit, and in most cases the headache disappeared, the temperature rose, the skin became warm and moist, and there was a return of energy so that the patient commented upon her sense of well-being.

321. Pregnancy and Coitus.

L. BALLIN (*Münch. med. Woch.*, August 3rd, 1929, p. 1293) states that the question of whether sexual intercourse is permissible during pregnancy is one on which medical opinion is divided, especially as regards the first half of the period. Of recent years statistics from various sources concerning several thousand women have been published showing that with few exceptions coitus has taken place during pregnancy, and in 25 per cent. throughout the whole period. Provided the woman was healthy, miscarriage occurred only in exceptional cases, and this could never undoubtedly be attributed to sexual intercourse. There does not, therefore, appear to be any medical justification for the general rule of abstinence laid down by some gynaecologists during the first

five months of pregnancy. In the last months, however, the sexual act may cause haemorrhage, premature rupture of the membranes, and fever during and after delivery. It is therefore advisable to prescribe moderation in sexual intercourse between the sixth and eighth months, and complete abstinence after the eighth month. Generally speaking, all authorities are agreed that coitus may be resumed four to six weeks after delivery. H. BÄR (ibid., p. 1292) records two cases of puerperal fever, one of which was fatal, where coitus a few hours before delivery was apparently the cause of infection, especially as in one case the same micro-organisms (Gram-positive diplococci) were found in the wife's vaginal secretion and on the husband's prepuce.

322. Procidentia Complicated by Rectal Prolapse.

D. J. CANNON (*Irish Journ. Med. Sci.*, August, 1929, p. 580) reports a case of procidentia complicated by rectal prolapse in a nulliparous woman, aged 58. Complete uterine prolapse was present, and several inches of the rectum protruded from the anus. After palliative treatment for six weeks an operation was performed, and the patient made a good recovery, except for the development of a rectocele which appeared about six weeks after the operation. Cannon remarks that this case raises the interesting questions of the pathology of rectocele, and the relation between rectocele and rectal prolapse. The pathology of rectocele, as usually defined by gynaecologists, is as follows. The perineum is torn and the tear becomes infected. In consequence there is a mild infection of the cellular tissue in the recto-vaginal septum. The walls of the two viscera adhere closely together, instead of passing freely over one another. When the patient strains at stool the rectal wall is prevented from sliding upwards over the faecal mass. Rectocele does not follow tears through the perineum which divide the anal sphincter, for when the sphincter is torn through the patient does not strain at stool. While this may be correct in the majority of cases, Cannon suggests that in a certain number of cases rectocele may be due to weakening, whether congenital or acquired, of the special band of connective tissue that passes from the rectum to the side walls of the pelvis, and which, he thinks, helps to keep the rectum at its proper level in the pelvis. This is the band of connective tissue which requires to be cut through in order to complete the operation of abdomino-perineal resection for cancer of the rectum. Should there be a weakening of this band from any cause, a rectocele may develop, provided that the anal sphincter is intact. Should there be a relaxation of the sphincter, a rectal prolapse will ensue.

323. Resuscitation of the Asphyxiated Newborn.

A. MATHIEU and A. HOLMAN (*Journ. Amer. Med. Assoc.*, June 8th, 1929, p. 1917) consider that the attempts at resuscitation of the asphyxiated newborn in vogue at present, such as beating, slapping, or plunging the infant into cold water, are either futile or actual deterrents that defeat their own purpose. Post-mortem examinations of the newborn that were living at birth reveal that 20 per cent. have atelectasis as the only demonstrable cause of death; therefore, it is logical to suppose that the majority of these would be amenable to a proper means of artificial respiration. Harrison advised the use of 5 per cent. carbon dioxide in oxygen administered by means of a tank and face mask, but this is considered an anatomical and economic impracticability. The mixture of carbon dioxide and oxygen should be given in such a way as to overcome the collapsibility of the embryonic larynx and trachea, and to prevent the gas going down into the stomach. The apparatus should be simple, cheap, easy to keep in order, and easily accessible at all times; the present authors maintain that the tracheal catheter fulfils all these requirements. Expired air contains sufficient oxygen and carbon dioxide to meet the needs of the asphyxiated infant. By means of the catheter all mucus, blood, and amniotic fluid can be withdrawn from the mouth, pharynx, and larynx before resuscitation is attempted. After the air passages have been freed from foreign material the gas (expired breath of the operator) can be placed at a location in the child's body where it will be readily available for use. Positive pressure is here of value, as it is delivered into the trachea and inflates the lungs; the air is warm and helps to maintain the body temperature. The authors state that the insertion and use of the tracheal catheter is simple and easy, and describe their technique. Negligence in maintaining the infant's body heat is the cause of some failures; a basin of warm water or soft warm blankets are adequate. Efforts at resuscitation should be continued as long as the heart beats, and may be supplemented with three minimal doses of a solution of pituitary extract and adrenaline. After the establishment of regular respiration, the child should be kept warm and observed closely for several hours for fear of subsequent respiratory failure; should this occur, the manœuvres must be repeated.

Pathology.

324. Effect of Exertion on Blood Sugar.

C. BRUUSGAARD (*Norsk Mag. f. Laegevid.*, July, 1929, p. 778), in order to determine the variations in blood sugar caused by severe muscular exercise, carried out an examination of athletes during training and contests (sprinting and long-distance competitions). The method employed was that of Hagedorn and Normann-Jensens. His conclusions were as follows. Exertions of short duration were constantly accompanied by an increase of blood sugar, the extent of this increase being considerably greater than has been previously stated, and partly due to emotional factors, since it was much less pronounced during training. Hypoglycaemia, therefore, could not be the cause of fatigue produced by exertion of short duration. When the exertion lasted more than three hours a decrease in the amount of blood sugar was constantly met with. As a rule the decrease was not very pronounced, since the organism has a remarkable capacity for keeping the blood sugar at a normal level. It was only severe exertions on an empty stomach that caused a pronounced hypoglycaemia. During severe exertions of long duration hypoglycaemia might be regarded as a factor in producing fatigue. Under such circumstances, therefore, sugar should be given, preferably in a concentrated watery solution. A study of the literature showed that the diabetic organism reacted in the same way as the normal. The variations, however, were considerably greater both as regards hyperglycaemia and hypoglycaemia.

325. The Reliability of Cultures taken at Necropsies.

H. F. HUNT, ETHEL BARROW, L. THOMPSON, and G. W. WALDRON (*Journ. Lab. and Clin. Med.*, July, 1929, p. 907) have made a bacteriological study of 567 post-mortem subjects. Blood cultures were taken from the pulmonary artery, and cultures were made from the liver, spleen, and other organs when indicated. From examination of their results the authors conclude that, in the case of bodies not subjected to refrigeration, no demonstrable post-mortem invasion of the blood or visceral organs occurs within twelve hours of death, and that cultures made from these situations before this time has elapsed may be regarded as being reliable. The former conclusion rests on the more or less constant ratio between the number of positive and the number of negative cultures taken at varying hours after death; since, however, the majority of cultures were taken within three hours of death, the ratios determined for the later hours are based on relatively few figures. Cultures taken from cadavers which, on macroscopical examination, showed no obvious foci of infection were almost invariably sterile. Cases of this type included such conditions as brain tumours, thyroid diseases, cardio-vascular diseases, and blood dyscrasias. Only once in 266 cases was a positive culture obtained—a case of lymphatic leukaemia. On the other hand, in an examination of 301 cadavers which showed definite foci of infection, such as peritonitis, abscess, meningitis, ulcerative colitis, and pneumonia accompanied by abscess formation, positive cultures were obtained from 172—that is, 57.1 per cent. From this study the authors conclude that post-mortem bacteriology is reliable, and may often be most valuable in ascertaining the cause of death.

326. Bactericidal Action of Tuberculous Serum.

P. COURMONT and H. GARDÈRE (*C. R. Soc. de Biologie*, July 5th, 1929, p. 817) have attempted to obtain some measure of the bactericidal power of the serum of tuberculous patients on the tubercle bacillus. A series of glycerin broth tubes was taken, and to each one was added a varying amount of the serum to be tested. The tubes were then inoculated with a strain of tubercle bacillus which grows homogeneously in a fluid medium, and the results were read after a fortnight. If no growth occurred in the tube containing broth *plus* one-eighth of the quantity of serum, the reaction was reported as + 8; growth in a tube containing equal quantities of broth and serum was apparently reported as 0. The serum of 37 patients was examined. (1) Sixteen patients had a high bactericidal titre, + 8 or + 4; in all these patients, except two who died, the evolution of the disease was very favourable, frequently passing on to a clinical cure. (2) Thirteen patients had a moderate titre, + 2; of this group five died. (3) Eight patients had a very low titre, + 1, or showed no evidence of bactericidal bodies by this technique; of this group six died. In the horse, an animal resistant to tuberculosis, the titre is said to be always high, + 8 or + 4; in the susceptible guinea-pig it is lower, + 2. In human beings showing no sign of clinical tuberculosis, and in patients who have recovered from tuberculosis, it is likewise + 2. The authors regard these observations as suggesting that the bactericidal power of the serum plays a considerable part in the defence of the host against tuberculosis.

de KUYPER'S

HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 233 years.

COLLENDER'S SPLINTS

(Patented in the Leading Countries of the World)

An evolution of the Thomas Splint—all the advantages of the Thomas Splint are preserved, with many important improvements, additions, and modifications.
They are supplied in strong fitted case, and enable 10 fractures simultaneously to be put up in any position obtainable by Thomas arm or leg Splints.
They provide the most modern methods of accurate extension, and safe transport of the patient is assured. Complete splints suited to limbs of any dimensions can be constructed in a few minutes from the component parts.

All members are interchangeable, standardised, numbered, and replaceable. They are made of Duralumin, which is untarnishable, exceedingly light in weight, and of great tensile strength. They can be immersed in sterilizing fluid without injury and can be used repeatedly.
Collender's Splints will be found invaluable for Hospital Emergency work and particularly to District Surgeons, Mines, Ranches, Lumber Camps; Railways, Shipping Companies, Industrial Plants, and all places remote from surgical help.

Descriptive booklet from:

WATSON BAKER COMPANY, WEST END LANE, BARNET, HERTS, ENGLAND.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

Clothes by
KEITH BRADBURY
including Ladies' Tailor-Mades

Overcoats *for* Autumn

£1 PER MONTH

Summer days are speeding away, the evenings are becoming chilly and instinctively one seeks the warmth and comfort of an overcoat. Dinners and dances, too, are taking the place of evening golf and tennis, and many suits of dress clothes, shabby or green with age, will need replacing.

A new overcoat, new dress wear, and perhaps a new lounge suit for the winter would cost at least 16 guineas, and how many men feel disposed to write a cheque for this amount so soon after the holidays, especially Doctors, who have to depend upon the financial recuperation of patients for payment of their accounts.

It is through the difficult times, such as now, that Keith Bradbury's system proves its usefulness, by enabling a Doctor to replenish his wardrobe with West End tailored clothes at attractive prices upon a monthly basis of payment, to suit his individual requirements.

Keith Bradbury, Ltd., have served the medical profession long enough to know that references and enquiries are superfluous—and to provide the usual cash or quarterly facilities for those who prefer them.

The appearance of medical men should be in keeping with the prestige of the profession, and it costs you nothing to write, to telephone, or call for full particulars of Keith Bradbury's £1 per month system of tailoring, which is helping an ever increasing number of Doctors to dress well without financial inconvenience.

Overcoats and Lounge Suits	from 5 gns.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

"The Rose Corset-Belt"

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health ... and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition.... MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

THE RESIDENTIAL TREATMENT OF ALCOHOLISM & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address)—WOODBRIDGE, SUFFOLK.

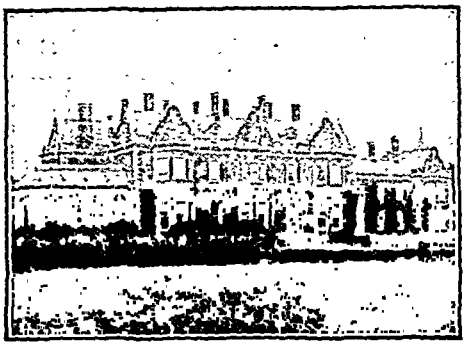
Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

Rendlesham Hall has 45 bedrooms, and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated Booklet, giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: Wickham Market 16.



RENDLESHAM HALL.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: The Most Hon. the Marquess of Exeter, C.M.G., A.D.C.

Medical Superintendent: Daniel F. Rambaut, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical Treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

BAGULEY SANATORIUM. (333 Beds.)

APPOINTMENT OF SENIOR ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified Medical Men for the position of Senior Assistant Medical Officer.

Every applicant must be a registered Medical Practitioner, under 40 years of age, and unmarried.

Applicants must have held Resident Hospital and Sanatorium appointments, and have had practical experience in the diagnosis and modern methods of treatment of tuberculosis; practical experience in radiology is desirable.

Salary £500 per annum, with board, residence, and laundry in addition.

The successful candidate would be required to take up duty on January 1st, 1930.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope, "Medical Officer, Baguley Sanatorium," must be addressed to the undersigned only, and not to members of the Committee or Council, and must reach him not later than Monday, the 28th instant.

The gentleman appointed will be required to pass a medical examination, to devote the whole of his time to the duties of his office, to take charge in the absence of the Medical Superintendent, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order,
F. E. WARBRECK HOWELL,
Town Clerk.

Town Hall,
Manchester. October 7th, 1929.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

BAGULEY SANATORIUM. (333 Beds.)

APPOINTMENT OF ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified Medical Men for the position of Assistant Medical Officer.

Every applicant must be a registered Medical Practitioner, under 40 years of age, and unmarried.

Preference will be given to applicants with previous Hospital experience; some experience of bacteriology or radiology is desirable.

Salary £350 per annum, with board, residence, and laundry in addition.

The appointment is made in the first instance for a period of twelve months, renewable at the expiration of that period.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope "Medical Officer, Baguley Sanatorium," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must reach him not later than Monday, October 28th.

The gentleman appointed will be required to pass a medical examination, to devote the whole of his time to the duties of the office, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order,
F. E. WARBRECK HOWELL,
Town Clerk.

Town Hall,
Manchester. October 7th, 1929.

County Borough of Bootle.

ASSISTANT SCHOOL MEDICAL OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited for the appointment of Assistant School Medical Officer and Assistant Medical Officer of Health (male) at a salary of £600 per annum, rising by £30 annually to a maximum of £750 per annum. Particulars of the duties (which include School Medical Inspection and the conduct of Maternity and Child Welfare Clinics) and forms of application may be obtained from the Medical Officer of Health, Town Hall, Bootle.

Applications, accompanied by copies only of not more than three testimonials, endorsed "Assistant Medical Officer," must be returned to me on or before October 19th.

Canvassing, either directly or indirectly, will disqualify candidates.

Town Hall, J. SPENCER TUMILTY,
Bootle. Town Clerk.
September 27th, 1929.

Birmingham Union.

SELLY OAK HOSPITAL.

CASUALTY OFFICER (Male).

Applications are invited from fully qualified medical practitioners for the appointment of Casualty Officer (male) at the Selly Oak Hospital, Birmingham.

The present Hospital accommodation is 550 beds, divided into General Medical, General Surgical, Gynæcological, Obstetrical, Children and Infectious sections. There is a completely [illegible] atory, also X-Ray, [illegible] and Sunlight De[illegible] perations are performed annually.

The appointment will be for a period of six months in the first instance, but may be extended at the end of that time.

The gentleman appointed will be required to assist at operations, administer anæsthetics, and undertake casualty work, and such other duties as may be assigned to him by the Medical Superintendent, and, should occasion arise, to assist at any of the other Institutions under the control of the Guardians.

The salary attached to the appointment is at the rate of £200 per annum, together with full residential emoluments (rations, apartments, laundry, and attendance).

A deduction of 2 per cent. will be made from the salary and value of emoluments under the provisions of the Poor Law Officers Superannuation Act, 1896, and for this purpose the emoluments are valued at £200 per annum.

Further particulars of the appointment may be obtained from the Medical Superintendent, Mr. R. P. S. Kitman, M.B., F.R.C.S.(Eng. & Edin.), at the Selly Oak Hospital.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, must be forwarded so as to reach me not later than Thursday, October 17th.

Union Offices, C. P. BEECH,
Edmund Street, Clerk to the
Birmingham. Guardians.
September 25th, 1929.

Monmouthshire County Council.

ASSISTANT MEDICAL OFFICER.

The Council invite applications from duly qualified Medical Practitioners holding a Diploma in Public Health and State Medicine, and not exceeding 35 years of age, for the appointment of Assistant Medical Officer (woman), to undertake mainly the work associated with (1) the Medical Inspection and Treatment of School Children; (2) Maternity and Child Welfare; and (3) the assessment of vision under the Blind Persons Act, 1920.

Special experience in refraction and ophthalmic work is essential.

Salary £500 per annum, rising by annual increments of £25 to £750, with third-class rail fares and reasonable subsistence allowance.

The successful candidate will be required to act under the direction and supervision of the County Medical Officer, to devote whole time to the service of the County Council, and to reside in such place as the Council may determine.

The requisite statutory meeting of the County Council has adopted the Local Government and Other Officers Superannuation Act, 1922, and when confirmed by the Minister of Health the post will be subject, as and from April 1st, 1930, to the provisions of the Act.

A schedule of the duties to be performed, together with conditions of appointment and a form of application, can be obtained from the undersigned, to whom applications, accompanied by copies of not more than three recent testimonials, are to be sent by November 1st.

County Hall, D. ROCYN JONES,
Newport, Mon. County Medical Officer.
October 7th, 1929.

County Borough of West Hartlepool.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications for the position of Assistant Medical Officer of Health are invited from duly registered medical men holding the Diploma of Public Health.

The candidate appointed, who will act under the direction [illegible] Officer of Heal[illegible] the work in [illegible] Child Welfare [illegible] Officer. In addition he will be required to undertake any duties in connection with the medical services of the Local Authority, which may from time to time be assigned to him by the Medical Officer.

Forms of application may be obtained from me.

The inclusive salary will be £600 per annum.

Applications, endorsed "Assistant Medical Officer of Health," must reach me not later than October 16th.

HAROLD W. STANTON,
September 30th, 1929. Town Clerk.

County Borough of St. Helens.

TUBERCULOSIS OFFICER.

Applications are invited for the above post. Duties will be mainly in connection with the Authority's Tuberculosis Scheme, including those of Resident Medical Officer at the Council's Tuberculosis Sanatorium, but the selected candidate will be required to perform such other duties as the Medical Officer of Health may direct.

Candidates must have had special experience in Tuberculosis (both pulmonary and non-pulmonary) from both clinical and administrative aspects, and the possession of a Diploma in Public Health is desirable.

Salary £600 per annum, with board residence.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the successful candidate passing the necessary medical examination.

Forms of application may be obtained from the Medical Officer of Health, Town Hall, St. Helens, and completed applications, accompained by copies of not more than three recent testimonials, should reach him not later than Saturday, October 26th.

Town Hall, FRANK HAUXWELL,
St. Helens. Medical Officer of Health.
October 7th, 1929.

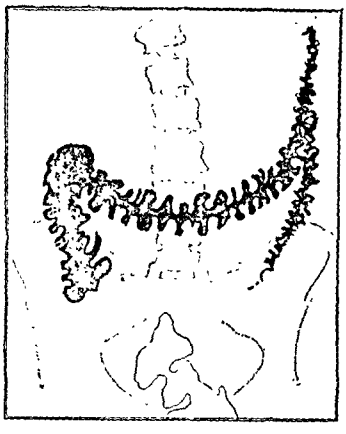
A one-third share is offered in a good-class general Practice averaging [illegible] p.a. Panel of 1,300. Cottage Hospital and [illegible] ing partner must be a gentleman and fond [illegible] 2 years' purchase.
4. SUSSEX.—In a very pretty district amidst delightful surroundings an old-established PRACTICE worth at present about £1,150 p.a., but offering exceptional scope for development. Panel of 525 and Union appt. Fees 3/6 upwards. Opposition 3½ miles distant. Rail-way station. Charming residence in its own grounds of 2½ acres [illegible] ws. Ample accommodation. Central [illegible] Freehold for sale. Prem. £1,700.
5. [illegible] RESORT.—Well-established PRAC-TICE, averaging about £600 p.a., easily worked, and capable of increase. Panel of 500. Fees 3/6 to 21/-. No midwifery. Suitable house can be rented at £85 p.a. Premium £1,000. Ill health reason for sale.
6. SOUTH-WEST COAST.—FAVOURITE HEALTH RESORT.—Good mixed PRACTICE, averaging over £700 p.a. and offering scope for in-crease. Panel of 720. Fees 5/- upwards. Very nice house, with 2 reception, 4—5 bedrooms, etc. Garden. Premium 2 years' purchase.
7. ESSEX.—Within fifteen miles of London.—Old-established unopposed and increasing PRACTICE, situated in a beautiful country district, and producing last year over £1,100, including Union £90, and panel, with mileage, £432. Comfortable house (professional accommo-dation, 2 sitting, 6 bedrooms, with h. and c. water laid on, etc.). Large garden. Rent £70 p.a. on lease. Electric light available. Pre-mium £1,650. Ill health reason for disposal.
8. NORTHANTS.—Unopposed Country PRACTICE, within easy reach of large town, old-established and averaging over £1,600 p.a., including about £675 from panel and £80 from appts. Fees from 2/6 to 21/-. Large house, with 3 reception, 6 bedrooms, etc. Electric light. Good garden. Garage. Vendor's freehold. Premium 1½ years' purchase.
9. WEST OF ENGLAND.—LAR[illegible] —A share representing about £900 p.a[illegible] n panel, is offered in a well-established [illegible]ctice. Fees 2/6 upwards. Suitable hous[illegible] rooms, etc. Garden. Garage. Rent on lease £40 p.a. Premium £1,200 cash and balance by arrangement.
10. HOME COUNTY.—Near the Sea.—Old-estab. unopposed Country PRACTICE in pretty district. Receipts last year over £1,100, in-cluding Union, etc., £55, and panel of 400. Railway station near. Good house in its own grounds of 10 acres (part is let for grazing, but could be sold for building purposes), containing 2 reception, 6 bedrooms, bathroom, etc. Water laid on and electric light avail-able. Price for freehold £2,100. Premium £1,625. Educational facilities, sport, etc.
11. DEATH VACANCY.—HANTS.—COUNTRY PRACTICE, at present producing about £480 p.a., but offering large scope. Panel of 280. Fees 3/6 to 10/6. Mid. from 3 gns. Convenient house, with 2 reception, 5 bedrooms, etc. Garden and garage. Can be rented on lease at £75 p.a. Premium £500. Locum in charge.
12. HERTS. — Better-class Country PRACTICE, within easy reach of London. Old-established, and patients are chiefly of the professional class. Average income £1,000 p.a., including panel of 480 and about £60 from appointments. Advice and medicine 3/6 to 10/6, visits 3/6 to 21/-. Not much midwifery. Exceptionally nice house, with every modern convenience and half an acre of garden. Price for freehold £2,700. Excellent sport, society, and schools. Prem. £1,500.
13. MIDLANDS.—In a clean thriving Hospital town (pop. 130,000), an old-established mixed-class PRACTICE worth last year £1,100, in-cluding panel producing over £400 p.a. and £150 from Public Medical Service. Large house, with ample accommodation, good garage, garden, etc. Vendor's leasehold having 31 years unexpired (ground rent £9 16s.). Price £1,500. Premium £1,650.
14. WILTS.—COUNTRY PRACTICE, on outskirts of large town. Well-establi[illegible] immediate past year over £1,630, includ[illegible]e and medicine 3/6, visits 5/-upwar[illegible]ouse, with good garden. Garage. Rent [illegible] £2,400.
15. NEW [illegible] a delightful and popular seaside resort (pop.: town over 17,000 and country 5,000, greatly augmented by visitors) on main line, a well-estab[illegible] p.a. for the past 5 years, including a[illegible] sultations fees 10/6. Mids. 4 to 10 [illegible] situated in excellent position and con[illegible] acre of garden, tennis court, etc. Can be leased. Excellent educational facilities. Sport of all kinds.
16. LONDON, S.W.—Within easy reach of Charing Cross.—Very old-established middle-class non-panel PRACTICE averaging over £2,000 p.a. Fees 2/6 to 10/6. Mids. 3 to 10 gns. (about 12 cases). Commodious house, with 2 reception, 5 bedrooms, etc. Garden. Rent on lease £65. Premium £3,100.
17. LONDON, WEST.—Good-class General PRACTICE, held by Vendor for the past 25 years. Gross cash receipts for past three years average £1,682. Fees 10/6 to 2 guineas. Only a few midwifery cases at from 10 to 20 guineas. Good house, with 3 public and 6 bedrooms, etc. Electric light. Garden. Garage. Rent on lease £150. Pre-mium £2,750.
18. NORTH LONDON. — Old-established good middle-class PRACTICE. Average gross cash receipts for past three years £2,572. Selected panel of 240. Fees from 5/- upwards. Mids. from 7 gns. (only a few cases yearly). Very good corner house, non-basement, with 3 reception, 5 bedrooms, etc. Price for Practice and house £5,000.
19. CORNWALL.—FAVOURITE COAST TOWN.—PARTNERSHIP.—A one-third share is offered in a well-established Practice, having good surgical scope. Average gross cash receipts £4,200 p.a. Panel of about 1,800 and good appts. Very nice house available on rental, or smaller house or rooms could be taken. Hospital and prospect of appt. on staff. Premium £2,400.
20. PARTNERSHIP.—SOUTH-EAST COAST.—A one-third share (with increase later) is offered in a well-established non-dispensing Practice situated in a popular residential town and health resort. Receipts for past three years average over £3,000, with good scope. Fees from 5/- to 21/-. Very little mid. Attractive house, with 4 recep-tion, 6 bedrooms, etc. Garden. Garage. Premium 2 years' purchase.
21. SOUTH-WEST OF ENGLAND.—SEAPORT TOWN.—PARTNERSHIP.—A one-sixth share is offered in a very old-estab. sound mixed-class Practice situated in residential outlying suburb. Average gross cash receipts for past three years over £6,700, including panel of 4,000, and appts. worth about £750. Excellent house, property of retiring partner, can be bought; or purchaser can select his own residence. Good sport and schools. Premium 2 years' purchase.
22. CARDIFF.—Old-established better-class non-dispensing worth last year about £1,400. Panel of 450. Fees from 5/- to 21/-. Very little midwifery. Good house in best part of the city. Can be rented on lease. Premium £2,000.
23. ESSEX.—Rapidly developing outlying suburb, within ten miles of the Bank.—Well-established and increasing PRACTICE. Income last year £2,274. Panel of 1,646. Fees 2/6 upwards. Very little midwifery, but large scope. Very good corner house, in excellent repair, with 2 reception, 5 bedrooms, separate professional rooms, etc. Electric light. Garden. Garage. Price for freehold £1,550. Prem. £3,600.
24. WITHIN 50 MILE[illegible] and increasing PRACTICE situated [illegible] pretty district. Income last year ov[illegible] 500, and appts. worth about £60[illegible]a. Exceptionally nice house can be bought, or smaller house available, which can be rented at £50 p.a. Good schools for boys. Premium 1½ years' pur-chase. Good scope for increase.
25. YORKS.—LARGE TOWN.—Old-established mainly working-class PRAC-TICE. Income £1,250. Panel of over 1,400. Fees 2/6 to 5/-. Well-situated house, with good garden. Price £1,500. Prem. £1,800.
26. LIVERPOOL.—Centrally situated old-established PRACTICE. Income about £1,500. Panel of over 2,500, worked from Branch Surgery. Visits and medicine from 3/6 to 7/6. Little midwifery. Large corner house, with garden and garage. Recently redecorated. Electric light and new hot water system throughout. Price, freehold, £2,000. Large scope for increase. Premium 1½ years' purchase.
27. SOUTH-WEST OF [illegible] —PARTNERSHIP.—A half share is for [illegible] non-panel, general, and surgical Practi[illegible] years over £5,000 p.a. Good house, [illegible] etc. Premium 2 years' purchase. Purchaser should hold the F.R.C.S.
28. GLOS.—LARGE TOWN.—PARTNERSHIP.—A half share of an old-established good-class non-dispensing Practice, owing to retirement through ill health of senior partner. Income about £5,000 with small select panel. Fees 5/- to 10/6. Purchaser should be about 40, married, and keen on midwifery. Good house available at low rental. Premium 2 years' purchase, part by instalments.
29. NORTH-WEST LONDON.—Within easy reach of Charing Cross.—Old-established mixed-class PRACTICE averaging over £2,000 p.a., in-cluding panel of about 1,400. Fees 2/6 to 10/6. Midwifery 3 to 15 gns. Six-roomed house, with bathroom, kitchen, etc. Rent on lease £85. Surgery premises (part let off) rented at £75 p.a. Could be worked as "lock-up." Premium 1½ years' purchase.
30. SOMERSET.—Increasing PRACTICE, situated in very pretty district. Income last year over £900, with good scope. Panel of nearly 400, and appts. worth about £260. Fees 2/6 to 15/-. Not much midwifery from 7 to 15 gns. Good house, with 2 reception, 5 bedrooms, etc. Garden. Price for freehold £1,275, part on mortgage. Excellent sport. Schools. Premium 1½ years' purchase.
[illegible] PRACTICE, producing this year at the [illegible] nel of 560. Good house, specially built and [illegible] 2 reception, 4 bedrooms, etc. Large garden. [illegible] old £1,700, part on mortgage. Prem. £1,550.

Full Schedule of Terms and Conditions will be forwarded on application.

Occult Constipation



Occult constipation (from an X-Ray) 24 hours after opaque barium meal. There has been one small stool as usual. Note the deep haustrations and partial dilatation of the cæcum.

THE menace of occult constipation lies in the fact that the patient may have regular daily evacuations, and is therefore unaware of the constant retention of fæcal matter, which may ultimately form a hard and deep coating on the intestinal wall, leaving but a small passage through which painful and partial evacuation takes place.

When headaches, lassitude, and the conditions usually associated with the development of intestinal toxæmia lead to the suspicion of hidden constipation, the reliance of many physicians is on AGAROL Brand Compound, *the original mineral oil and agar-agar emulsion.* Combining lubrication with softening of the fæcal mass and gentle peristaltic stimulation, AGAROL Brand Compound is particularly indicated in cases of occult constipation — because of its positive, yet gentle action, without habit formation.

AGAROL Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion and has these special advantages:

Perfectly homogenized and stable; pleasant taste without artificial flavouring; freedom from sugar, alkalies and alcohol; no contra-indications; no oil leakage; no griping or pain; no nausea or gastric disturbances; not habit forming.

INTESTINAL SUBINFECTION

SALVITAE is the key whereby the physician may control elimination and alkalinization, thus dealing fundamentally and effectively with Intestinal Subinfection, Toxæmia, Acidosis, Uric-acidæmia, and Constipation.

It is indicated in a large number of disorders characterized by, and more or less dependent upon, faulty metabolism, imperfect elimination, and disturbances of the acid-base equilibrium of the body.

Dental Sepsis

ALTHOUGH matters concerning the teeth belong primarily to the sphere of the dental surgeon, pathological conditions arising from dental sepsis are constantly encountered by the physician. This is particularly true in the case of rheumatic affections, especially those of the arthritic type. Other conditions attributed to dental sepsis are anæmia, including septic anæmia, atony and dilatation of the stomach, neurasthenia, and numerous affections of the eye.

In these cases much can be done to secure and maintain a healthy condition of the mouth. If immediate dental treatment cannot be undertaken the measures adopted should include the use, at least twice daily, of a tooth paste of known germicidal power. Such a tooth paste is Euthymol Tooth Paste, which is made with the same exacting care as is exercised in the manufacture of Parke, Davis & Co.'s medicinal preparations. It is surprising how beneficial the simple massage of the gums with this dentifrice can be. Every batch is tested bacteriologically to ensure a standard carbolic co-efficiency of not less than 0·14.

Euthymol
TOOTH PASTE

A full-sized tube of this tooth paste will be sent to any physician who may care to test its value.

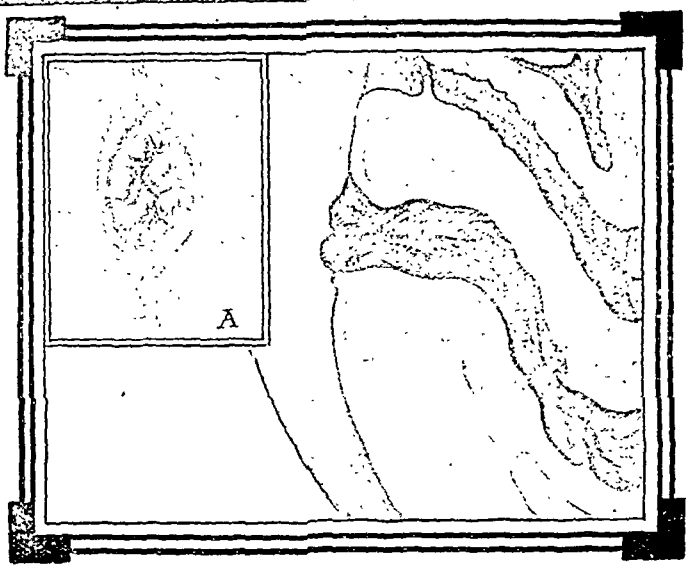
D



...In the Management of Hemorrhoids

palliative treatment is generally directed to removing congestion of the portal circulation and diminishing the size of the piles.

Applied as hot as can be comfortably borne, Antiphlogistine constitutes a palliative *par excellence* in the alleviation of the pain, inflammation, and distressing tenesmus caused by external piles.

The thermotherapeutic and bacteriostatic properties of

Antiphlogistine

will prevent the development of ulceration, induce relaxation of the inflamed hemorrhoidal veins, relieve the discomfort due to local pressure and thereby facilitate the normal act of defecation. Coupled with appropriate diet and exercise, the routine application of this plastic dressing will usually suffice to yield positive results in the management of hemorrhoids.

Sample of Antiphlogistine and Clinical Data mailed to the Physician on request.

J. & A. CHURCHILL

THE EMPIRE SERIES

THE CAUSES AND PREVENTION of MATERNAL MORTALITY
HENRY JELLETT, B.A., M.D., F.R.C.P.I. 15s.

DISEASES OF THE BLOOD
A. PINEY, M.D. 12s. 6d.

SURGICAL ANATOMY
GRANT MASSIE, M.B., M.S., F.R.C.S. 15s.

A TEXT-BOOK OF BIOCHEMISTRY
A. T. CAMERON, D.Sc., F.I.C., F.R.C.S. Second Edition. 15s.

MEDICAL BACTERIOLOGY
Descriptive and Applied

L. E. H. WHITBY, M.D., D.P.H. 10s. 6d.

A HANDBOOK OF CLINICAL CHEMICAL PATHOLOGY
F. S. FOWWEATHER, M.D., M.Sc., D.P.H. 8s. 6d.

SURGERY IN THE TROPICS
SIR FRANK P. CONNOR, D.S.O., F.R.C.S. 12s. 6d.

THE PRACTICE of REFRACTION
W. STEWART DUKE-ELDER, M.A., D.Sc., M.D., F.R.C.S. 12s. 6d.

NOW READY, NEW (FIFTH) EDITION. 1,054 pages. ONE GUINEA. Postage 1s.

STARLING'S PHYSIOLOGY
Edited and Revised by C. LOVATT EVANS, D.Sc., F.R.C.P., F.R.S., Jodrell Professor of Physiology in University College, London. With chapters on the Central Nervous System and Sense Organs revised by H. HARTRIDGE, M.A., M.D., Sc.D., F.R.S., Professor of Physiology, St. Bartholomew's Medical College.

SECOND EDITION. 274 Illustrations, 4 Coloured Plates. 18s., postage 9d.

THE QUEEN CHARLOTTE'S PRACTICE OF OBSTETRICS
By J. B. BANISTER, M.D., C. S. LANE-ROBERTS, M.S., A. W. BOURNE, M.B., L. G. PHILLIPS, M.S., T. B. DAVIES, M.D., L. C. RIVETT, M.C., F.R.C.S.
(Members of the Staff of the Hospital).

TWO NEW EDITIONS IN THE RECENT ADVANCES SERIES

5 EDITIONS in 5 YEARS

FIFTH EDITION. 48 Illus. 12s. 6d., post. 6d.
By G. E. BEAUMONT, D.M., F.R.C.P., D.P.H., and E. C. DODDS, M.V.O., M.D., B.S., Ph.D.

MEDICINE

SECOND EDITION. 115 Illustrations. 15s., postage 9d.
By W. HENEAGE OGILVIE, M.A., M.D., M.Ch., F.R.C.S.

SURGERY

SEVENTH EDITION. 900 Illustrations (13 in Colour). Two Volumes. 70s., postage 1s. 3d.

ROWLANDS AND TURNER'S OPERATIONS OF SURGERY
"This is probably the most important modern text-book on Operative Surgery published by British Surgeons.
"The volumes are not only safe as a book of reference, but of the greatest value to the general surgeon. The searching and detailed revision which has been carried out in the last edition does great credit to the ability and industry of the authors."—PRACTITIONER.

NOW READY. 3s. 6d., postage 3d.

ELEMENTARY ANATOMY AND PHYSIOLOGY FOR NURSES
By P. M. LODGE, Sister Tutor, General Hospital, Birmingham.

THIRD EDITION. 101 Illus. 36s., post. 9d.

FALTA'S ENDOCRINE DISEASES:
Their Diagnosis and Treatment

183 Illustrations. 15s. net, postage 9d.

FORENSIC MEDICINE ILLUSTRATED BY PHOTOGRAPHS
AND DESCRIPTIVE CASES

By HARVEY LITTLEJOHN, late Professor, Forensic Medicine, Edinburgh University.

"In so far as a Practitioner makes a special study of the medico-legal aspect of his many-sided practice, this volume will be of value to him, while every district or police medical officer would be the better equipped by its possession."—THE LANCET.

FIFTH EDITION. 21 Plates 313 Text-figures. 19s., Postage 9d.

PARSONS' DISEASES OF THE EYE
"The student has in this book all that he is likely to require before he begins to specialise, and no one could wish for a more concise and readable composition of the present-day orthodox teaching of ophthalmology."—THE LANCET.

12 Coloured Plates, and 191 Illustrations in the Text. 12s. 6d., postage 9d.

A HANDBOOK OF OPHTHALMOLOGY
By HUMPHREY NEAME, F.R.C.S., Ophthalmic Surgeon, University College Hospital; and F. A. WILLIAMSON-NOBLE, F.R.C.S., Assistant Ophthalmic Surgeon, St. Mary's Hospital.

By Prof. R. T. HEWLETT
King's College, London

BACTERIOLOGY
EIGHTH EDITION. 38 Plates, 63 Text-figures. 18s. net, postage 9d.

PATHOLOGY General and Special
FIFTH EDITION. 48 Plates, 12 Text-figures. 18s. net, postage 9d.

PREVENTIVE MEDICINE
12 Charts, 5 Diagrams. 18s. net, postage 9d.

33 Illustrations. 18s., postage 9d.

THE CHEMICAL ANALYSIS OF FOODS
A Practical Treatise on the Examination of Foodstuffs and the Detection of Adulterants

By H. E. COX, M.Sc., Ph.D., F.I.C., Public Analyst, Metropolitan Borough of Hampstead.
"The whole book is thoroughly practical, and describes in an intelligible manner methods of food analysis which can be trusted to give reliable results."—THE LANCET.

NINTH EDITION. 8 Plates, 273 Illustrations. 28s., postage 9d.

PRACTICAL PHYSIOLOGICAL CHEMISTRY
By P. B. HAWK, M.S., Ph.D., President of the Food Research Labs. Inc., New York City; and O. BERGEIM, M.S., Ph.D., Asst. Prof. of Physiological Chemistry, University of Illinois, College of Medicine, Chicago.

London: 40, Gloucester Place, Portman Square, W.1

LEWIS'S PUBLICATIONS

RECENTLY PUBLISHED. FIFTH EDITION. Revised and greatly enlarged. Medium 8vo. With 249 Illustrations. 31s. 6d. net; postage 9d.

THE DIAGNOSTICS AND TREATMENT OF TROPICAL DISEASES

A COMPENDIUM OF TROPICAL AND OTHER EXOTIC DISEASES.

By E. R. STITT, A.B., Ph.G., M.D., Rear-Admiral, Medical Corps, and Surgeon-General, U.S. Navy; Graduate London School of Tropical Medicine, etc.

"A very wide field is covered . . . very valuable addition to the text-books of Tropical Medicine."—TROPICAL DISEASES BULLETIN.

BY THE SAME AUTHOR.

EIGHTH EDITION. Revised and Enlarged. With 1 Plate and 211 Illustrations, containing 683 Figures. Post 8vo. 24s. net; postage 9d.

PRACTICAL BACTERIOLOGY, BLOOD WORK, AND ANIMAL PARASITOLOGY

INCLUDING BACTERIOLOGICAL KEYS, ZOOLOGICAL TABLES, AND EXPLANATORY CLINICAL NOTES.

"This is essentially the practical pathologist's handbook."—LANCET.

With 176 Illustrations contained in 52 Plates. Crown 4to. 7s. 6d. net; postage 6d.

ELEMENTARY PATHOLOGICAL HISTOLOGY

By W. G. BARNARD, M.R.C.S.Eng., Pathologist University College Hospital.

". . . will certainly be deservedly popular with students. It is beautifully produced and inexpensive."—LANCET.

THIRD EDITION. Foolscap 8vo. 10s. net; postage 4d.

LONDON HOSPITAL LECTURES ON

FORENSIC MEDICINE AND TOXICOLOGY

By the late F. J. SMITH, M.A., M.D.Oxon., F.R.C.P.Lond., F.R.C.S.Eng. Revised by G. JONES, M.B.Oxon., M.R.C.S., D.P.H.

". . . a surprising amount of material of the greatest use to students. . . . The whole range of forensic medicine is covered."—LANCET.

RECENTLY PUBLISHED. Demy 8vo. 5s. net; postage 4d.

MEDICO-LEGAL PROBLEMS

By Lord RIDDELL.

CONTENTS: Legal Responsibility of the Surgeon; Ethical, Legal, and Medical Aspects of Abortion; The Law and Ethics of Medical Confidences; Sterilization of the Unfit.

". . . The facts and tendencies are set forth clearly and impartially . . . an unquestionable success."—LANCET.

JUST PUBLISHED. SEVENTH EDITION. With New Illustrations (mostly in colour). Demy 8vo. 7s. 6d. net; postage 5d.

LANDMARKS AND SURFACE-MARKINGS OF THE HUMAN BODY.

By L. BATHE RAWLING, M.B., B.C.Cantab., F.R.C.S.Eng., Surgeon to St. Bartholomew's Hospital, etc.

Extract from Review of previous editions:—"This edition will doubtless be as popular as its predecessors, both with students and surgeons."

BRITISH MEDICAL JOURNAL.

SECOND EDITION. Thoroughly Revised. With 159 Illustrations (6 in Colours) from original Drawings and Photographs. Demy 8vo. 12s. 6d. net; postage 9d.

THE PATHOLOGY OF TUMOURS

By E. H. KETTLE, M.D., B.S.Lond., Professor of Pathology, University of London, St. Bartholomew's Hospital Medical College, etc.

"Even better than before. The book is excellently put together."

BRITISH MEDICAL JOURNAL.

With 25 Illustrations, including 17 Plates. 9s. net; postage 5d.

STERILITY IN WOMEN Diagnosis and Treatment

By SIDNEY FORSDIKE, M.D., B.S.Lond., F.R.C.S.Eng. and Edin., Surgeon to the Hospital for Women, Soho Square, London; Gynæcological Surgeon to the Kensington, Fulham, and Chelsea Hospital; Author of "The Effects of Radium upon Living Tissues," etc.

". . . results are given and discussed fairly and judicially . . . the book can be recommended."—BRITISH MEDICAL JOURNAL.

DISEASES OF THE HEART

THEIR DIAGNOSIS, PROGNOSIS, AND TREATMENT BY MODERN METHODS.

With chapters on the Ink Polygraph, Clinical Electro-Cardiography, X-Ray Examination, and Anæsthesia in relation to Cardio-Vascular Affections.

By FREDERICK W. PRICE, M.D., F.R.S.(Edin.),

Physician to the National Hospital for Diseases of the Heart; Consulting Physician to the Royal Northern Hospital, London.

Demy 8vo. Pp. 534. With 249 text figures, including 32 sphygmograms, 92 polygraphic tracings, and 87 electro-cardiograms.

NEW SECOND EDITION, 21s. net.

"By great care and by the use of an amazing amount of material, he has accomplished what many readers have been waiting for, giving us a complete account of the diagnosis, prognosis, and treatment of heart diseases by modern methods in association with all the invaluable teaching bequeathed to us by the older masters of clinical observations."—LANCET.

"The most valuable and comprehensive guide to the study of Cardiology with which we are acquainted."—NEW YORK MEDICAL JOURNAL AND RECORD.

"We think that most of our readers engaged in general practice will find this work extremely useful."—THE JOURNAL OF CLINICAL RESEARCH.

"In our opinion the book is indisputably the most authoritative contribution to Cardiology of our time."—FRANCO-BRITISH MEDICAL REVIEW.

"A book which we believe is destined to remain the standard work on Cardiology for many years to come."—AMERICAN MEDICINE.

"The second edition of this popular work on heart disease bears evidence of thorough revision, while the essentially clinical standpoint of the writer is maintained."—EDINBURGH MEDICAL JOURNAL.

"It may be said at once that the book adequately fulfils the purpose it has in view and is a perfectly sound, lucid, and reliable guide."—NEWCASTLE MEDICAL JOURNAL.

"Well-written, concise, and complete, containing a wealth of practical information. Obviously based upon the author's own experience and investigative work."—SURGERY, GYNECOLOGY, AND OBSTETRICS (Official Journal of the American College of Surgeons).

"Dr. Price is to be congratulated again on the reappearance in its second edition of his distinguished contribution to the increasingly important subject of Cardiology."—THE CANADIAN JOURNAL OF MEDICINE AND SURGERY.

OXFORD UNIVERSITY PRESS, Amen House, Warwick Square, London, E.C.4.

JUST PUBLISHED. FIFTH EDITION. Crown 8vo. 4/- net, postage 2d.

THE INJECTION TREATMENT OF VARICOSE VEINS

By A. H. DOUTHWAITE, M.D., F.R.C.P.Lond.

Extracts from Press Notices to previous Editions:

". . . most readable and clear . . . we can commend the book most heartily to our readers."—Glasg. Med. Journ.

"The book is most valuable to the general practitioner."—Prescriber.

"The book is concise, practical, and contains many interesting clinical facts."—Journ. of Roy. Naval Med. Service.

BY THE SAME AUTHOR.

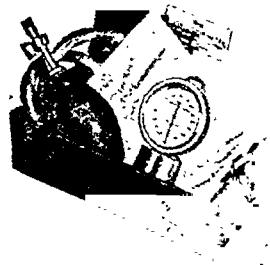
1 HILL PLACE EDINBURGH

Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.



Care should be taken to avoid close imitations. Look for the trade mark 'TYCOS' engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

SHOCK PROOF X-RAY APPARATUS

An epochal development in apparatus for medical diagnosis

THE Victor Shock Proof X-Ray apparatus, the latest development emanating from the Victor Research and Engineering Departments, is now in production and available to the profession.

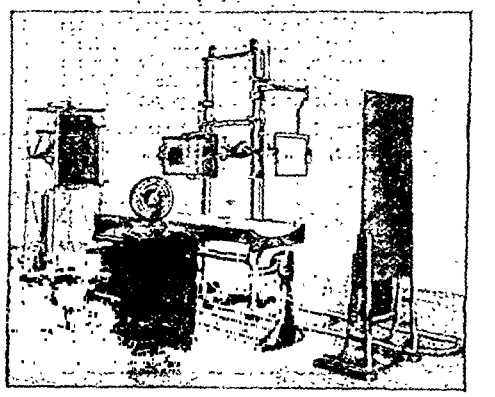
As its name implies, this X-ray unit is absolutely safe against any possibility of operator or patient coming in contact with electric current on any part of the apparatus—the first complete combination X-ray outfit in the world to incorporate this feature.

This development, the culmination of years of research and engineering efforts, answers the long-standing query of roentgenologists the world over: How can it possibly be accomplished? It is now a realization.

Complete insulation of the high voltage current (both the X-ray tube and high voltage transformer are immersed in oil and sealed in the same container) has permitted a revolution in apparatus design. The result is, a flexibility that permits of technic never before possible in X-ray diagnosis.

Unequalled facilities for research and experimental engineering have made possible this epochal development.

The Victor Shock Proof X-Ray Unit is submitted in the sincere belief that it is a direct contribution to the X-ray art, in that it offers a means of doing the work more quickly and conveniently, with absolute safety, and with assurance of consistently better end-results—contributing toward more certain diagnosis and a better medical service that must obviously follow.



- Shock proof.
- Silent operation.
- Compact.
- Self-contained.
- Greater flexibility.
- Increased diagnostic range.
- Eliminates overhead system.
- Longer tube life.
- Same tube used over and under table.
- Not affected by altitude or humidity.
- Introduces a new principle of control.
- Consistent results.
- Complete diagnostic service.
- Unit construction permits variation of installation according to specialty.
- No danger around ether, when setting fractures, etc.

We shall be pleased to demonstrate the Shock Proof Apparatus to you at any time.

(Free delivered in Great Britain).

"For nearly two years I have been treating angina pectoris by quartz light therapy with excellent results. The majority of my 34 cases were typical angina pectoris ambulatoria.

"When we consider the harmful effects of the attacks on the heart itself, on the general circulation, and on the mind of the patient, then such a treatment, which lessens the frequency of the attacks or diminishes their severity, and which indeed obviates them entirely in many cases, can be designated nothing less than causal. The impression is that in many cases a vicious circle is suddenly broken.

"The excellent mental effects also should not be underestimated. Patients, who for months did not dare walk, and felt the Damoclean sword of sudden death from heart disease hanging over their heads, breathe freely again, and feel themselves restored to life."

(Dr. Ernst Freund of Vienna University Clinic—(*Wiener klinische Wochenschrift*, 1928.)

BELLE VUE SPA

TREFRIW, NORTH WALES.

(Railway Station: Llanrwst and Trefriw.)

ARTHRITIS.
AMBULATORY TREATMENT.

Mobility and freedom from pain in crippling arthritis of the hip and knee even after shortening and contracture have occurred.

This is the special achievement of BELLE VUE SPA; secured by Hoefftcke's extension appliances, which maintain continuous extension by night and by day.

The appliance permits the patient to walk, and not only takes the body weight but replaces the normal state of compression of the leg by one of active stretching.

There is no other satisfactory way of combining movement with extension.

The method secures:

1. Extension without muscle loss inevitable when the patient is kept in bed.
2. Extension without the vascular stasis which occurs when a joint is kept at rest,

AND

MOVEMENT WITHOUT PAIN.

The result is rapid reconstruction of the joint with astounding restoration of function in those advanced cases which have hitherto seemed hopeless and incurable.

BELLE VUE SPA is well equipped for auxiliary treatment by massage, electricity, diet, light, etc., and full advantage is taken of the tonic virtues of its chalybeate waters.

CLINICAL RESEARCH ASSOCIATION. LABORATORY REPORT No. 31140.

ANALYSIS OF BELLE VUE SPA WATERS (MIXED).

Ferrous Sulphate	510.20 grains per gallon.
Aluminium Sulphate	48.56

In order that Doctors all over the country may test the tea their colleagues have so generously recommended, we will send ¼-lb. free to any medical man who will write for it. This offer applies solely to members of the Medical Profession

DOCTOR'S CHINA TEA

FOR many years Doctors have recommended our China Tea to Invalids and Dyspeptics when ordinary tea was out of the question. The Medical Press, too, has commented frequently upon the merits of this particular blend—and so we call it DOCTOR'S China Tea.

It is a perfect blend of the finest China leaf with all excess tannin eliminated.

Invalids and dyspeptics can drink it with no ill effects.

HARDEN BROS. & LINDSAY, LTD.
(Dept. 153), 30/34, Mincing Lane, London, E.C.3.

Famous as The Food of Royal Infants

also for invalids, the aged, and all persons of weak digestion

ROBB'S NURSERY BISCUITS have no equal. Easy of assimilation, a nourishing and sustaining diet, its appetising flavour is greatly appreciated by both young and old. Very welcome as a substitute for the ordinary bread-and-milk diet. Can also be lightly baked, with eggs and milk, to supply a delicious custard pudding

Robb's NURSERY BISCUITS

Highly recommended by eminent Accoucheurs and Physicians throughout the world as the most reliable food for Infants over six or seven months.

ROBB'S NURSERY BISCUIT POWDER is recommended when a feeding bottle is to be used, also as a diet for invalids.

ROBB'S DIGESTIVE RUSKS, TOPS and BOTTOMS, GINGER NUTS, and CHARCOAL BISCUITS are specially recommended for invalids and convalescents.

Send for large free sample and descriptive booklet, etc.

KEROL
CAPSULES

A prompt, painless eliminant and anti-acid.

One or two drachms of Sal Hepatica induces quick, painless and complete evacuation, which eliminates all toxic substances, reduces the blood pressure and renders the blood and urine alkaline. ¶ The toxic amino-acids present in the system which result in diabetes, rheumatism, gout, sciatica, lumbago, neuritis and all other disorders associated with acidosis, can be eliminated daily by the exhibition of Sal Hepatica. ¶ Sal Hepatica is non-habit-forming.

Sal Hepatica
the proved medicinal saline laxative and cholagogue.

¶ Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession, on application to

BRISTOL-MYERS COMPANY, 112, Cheapside, London, E.C.2

The Doctor orders Thermogene because:

(1) He knows it to be cleanly in use; whereas poultices and liniments soil clothes and skin, thus making examination with hand or stethoscope both unpleasant and difficult.

(2) He knows it to be fool-proof. It is always ready, and calls for no skill in preparation or application. It is never too hot, and cannot get cold and clammy. Scalding and chilling are alike impossible.

(3) He knows that, in addition to—or because of—its definite therapeutic action in promoting surface circulation and in stimulating healthy metabolism it invariably comforts and soothes the patient, and eases his pain.

THERMOGENE
MEDICATED WADDING

is carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

A full-size box of "Thermogene" with an interesting booklet on "Surface Therapy" will be sent free to any medical man who is unfamiliar with "Thermogene" and its many uses in practice. The Thermogene Co., Ltd., Queen's Rd., Hayward's Heath, Sussex

Local Anæsthesia in Surgical Practice

REDUCTION OF FRACTURE.

Typical Case.

M. S. C., male, aged 16 years.

Diagnosis: Fracture-dislocation of the shoulder-joint.

Operation: Open operation and reduction of fracture and fixation of fragments.

Anæsthesia: Brachial block 10 c.c. 2 per cent. Novocain-Adrenaline solution and local infiltration 60 c.c. of 1 per cent. Novocain solution. The anæsthesia was absolute.

Operation: The deltoid was split and the head of the humerus was reduced into its socket. The humeral shaft was adjusted to the head and a screw inserted diagonally through the shaft and into the head of the bone.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (FAIT).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 265, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Ample supplies of Novocain are available for the use of Surgeons at all the chief Hospitals. Specify "Novocain" for your next operation.

Does not contain Cocaine, and does not come under the Dangerous Drugs Act.

Cremo - Carbonates

(Tri-Carb-Cream-Mulford)

Effective
Non-Caustic
Palatable

CREMO-CARBONATES presents certain unique features which warrant its preference whenever an antacid and corrective is indicated. For the first time the well-known protectives and antacids, bismuth, magnesia, and lime are supplied as a suspension of particles of colloidal dimensions.

Its colloidal nature gives it maximum covering power superior to that of a mere mechanical mixture of bismuth, magnesium, and calcium.

CREMO-CARBONATES is a soothing, antacid corrective and digestant, particularly useful in the treatment of hyperacidity accompanied by flatulence and of any other conditions where there is excessive secretion of the gastric juices.

In Infancy

WHETHER the child be breast-fed or bottle-fed, constipation is often a troublesome feature. Castor oil and other purgatives, or aperients, while securing a prompt action of the bowels, possess certain definite disadvantages with which the practitioner is fully acquainted.

"Cristolax," a combination of 50% of the purest medicinal paraffin of correct viscosity and 50% "Wander" Dry Malt Extract, is of special value for infants, particularly for those who are artificially fed.

One teaspoonful dissolved in three feeds a day, no matter whether they consist of milk or infants' food, renders the feeds more easily digestible, prevents the formation of hard indigestible clots, and keeps the bowels in a regular and sweet condition.

"Cristolax" is also an admirable preparation for the nursing mother, both during gestation and the lying-in period. Its use ensures regular and adequate defecation without griping, straining, or harmful effect upon the child.

REGETHERM POULTICE

(Cataplasma Kaolini. B.P.C.)

CLEAN & CONVENIENT IN USE

More certain in its action than the old-fashioned poultice.

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover, the ingredients are so balanced that this action does not set up any counter-irritation, but allays pain, ensures an even circulation through the congested areas, and thus induces natural and pain-free rest.

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices, and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial, or of deep-seated origin.

PRICE 2/- PER 1-lb. TIN

(NOTE THE WEIGHT).

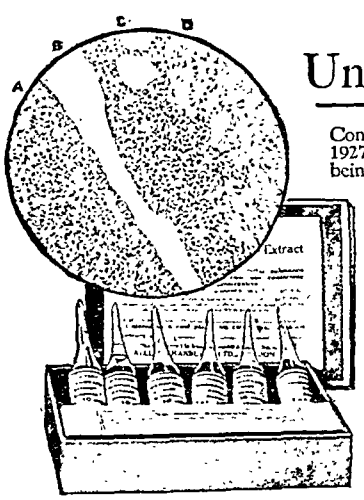
Denotes

Unvarying Pituitary Extract



Conforming to the requirements of the Therapeutic Substances Regulations, 1927, 'Pitibulin' is prepared according to the official standards, its activity being now expressed in terms of the accepted unit.

As heretofore, 'Pitibulin' maintains the stringently high criteria of therapeutic efficiency, safety in use and stability, self-imposed by its manufacturers—qualities which have given it its high place in the esteem of physicians.

'Pitibulin' retains its reputation as the Pituitary Extract which can be relied on in emergency.

Micro-photograph of section of Pituitary showing

(A) pars anterior
(B) inter-glandular cleft
(C) pars intermedia (posterior lobe)
(D) pars nervosa (posterior lobe)

'Pitibulin' is supplied in Ampoules containing 2.5, 5, and 10 units.

Literature giving fuller particulars of the therapeutic applications of 'Pitibulin' will be sent on request.

Produces normal functioning of the entire glandular system

COMPOSITION. Protonuclein is the pioneer organo-therapeutic product, and the popularity it enjoys to-day, a quarter of a century after its introduction to the medical profession, speaks eloquently for the sound reasoning that was responsible for its inception. Protonuclein is a true pluri-glandular product, consisting of a physiological association of those glandular structures particularly rich in nuclear material, namely the Thyroid, Thymus, Spleen, Pancreas, Stomach, Salivary Lymphatics and Brain (including the Pineal and Pituitary).

INDICATIONS. Protonuclein restores, regulates and augments the activity of glands or organs of the internal secretory system that may be apathetic, deficient or deranged.

FORMS. Protonuclein is issued to the Medical profession in tablets. Bottles of 100, 500 and 1000. Stocked by all first-class Pharmacists.

Samples and Descriptive Literature from Sole Distributing Agents for U.K. and Irish Free State: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

T.I.P. (Tetra-Iodo-Phenolphthalein B.D.H.)

For use in cholecystography T.I.P., in the form of its sodium salt, is prepared in an absolutely pure state specially for visualisation of the gall bladder. T.I.P. is issued for oral and for intravenous administration, every batch being tested physiologically before issue.

BARIUM SULPHATE B.D.H.

A product of extreme purity manufactured specially for the production of a solid barium meal for use in X-ray diagnosis. It is a thoroughly dependable product both in regard to its efficacy and to its freedom from toxicity.

SHADOFORM

Literature on request

A liquid barium meal is often required at short notice, and Shadoform is manufactured to meet this demand. It is a soft powder which, on mixing with water, gives a meal of cream-like consistency. The advantage of the Shadoform meal lies in the fact that it remains in suspension for a very long time.

THE BRITISH DRUG HOUSES LTD. LONDON N.1 X/R4

A NEW PREPARATION

Colloidal Calcium with Ostelin vitamin D

Clinical Indication.—In vasomotor skin affections, *chilblains*, chilblain circulation, urticaria, in gross nutritional failure occurring in debility, diseases, and also in delayed union of fracture, these Ampoules have proved of value.

The introduction of this preparation of Colloidal Calcium and Vitamin D for hypodermic injection places at the disposal of the practitioner a method of treatment, the value and applicability of which will at once be apparent in a large and varied class of cases.

The presence of the Vitamin D in addition to the Calcium, besides giving a very pronounced tonic effect, rationalises the administration of Calcium and further prolongs the effect, as it facilitates the absorption and utilisation of Calcium from the bowel.

Price Five Shillings per Box of Six Ampoules.

"COMMON COLD"

Every year in September and October we find an increasing demand for EVANS' COMMON COLD VACCINE for Prophylaxis. Built up of strains of the various organisms usually found in the nose and mouth in proportion to their frequency of occurrence, this Vaccine is now generally recognized to be of extreme value in the majority of cases. A large degree of the success of Evans' Vaccine is undoubtedly due to the fact that in our Pathological Laboratory we possess facilities for collecting the strains from the locality in which the Vaccine is to be used.

It is recommended that the prophylactic course be commenced a few weeks before the season during which the person is usually susceptible so that immunity may be established in good time.

A weaker dilution for Curative purposes is also supplied.

PRICES OF BOTH STRENGTHS:

1 c.c. Ampoules	2/6 each
Three graduated doses	7/- per box
Six graduated doses	13/6 per box

An Explanation of the latest Scientific Ideas in Infant Feeding

New facts—New discoveries
New Health Safeguards.

Doctors, Superintendents of Infant Clinics, Nurses, and Dietists are now insisting that for bottle-fed babies it is absolutely essential that the food given should be protected from contamination in every possible way. It is with this object in mind that Libby's Milk is prepared under strictly scientific and hygienic conditions, so that the milk in the sealed container shall be as pure and as nourishing as if germs and microbes had never existed.

The value of Libby's Evaporated Milk as a source of the essential vitamins is established by scientific experiment. The presence of vitamins A and B has been demonstrated by research, and also its value as a source of calcium, phosphorus, and nitrogen, so essential for bone and muscle growth.

It is a fact, scientifically established, that babies fed on Libby's Milk according to the Libby directions do not suffer from impaired digestion, and its use minimises the possibility of those troublesome daily and nightly accumulations of wind which invariably cause so much pain and distress.

There is a scientific reason for the mildness and remarkable ease of digestion of Libby's Milk. It is "homogenized." That is to say, as Libby's Milk is produced by a scientific method, which is in itself a wonderful discovery, the fat particles are broken up under extreme pressure, through microscopically fine apertures. The result is that the butter fat is completely emulsified and perfectly distributed throughout the milk. Then by sterilization, after the milk is in the container, you have a milk ideally suitable for babies and children of all ages. It is as safe and easily digested by infants as mother's milk.

£1,000

will be paid to any hospital or other public charity if it can be proved that the claims made for Libby's Milk are not in accordance with scientific facts.

Established in 1868.

Libby's Evaporated Milk

LIBBY, McNEILL & LIBBY, Ltd.
(Dept. 22), 8, Great Tower Street, E.C.3

I.F. 1c-29

"SMILER"

INFANT MORTALITY

has been greatly reduced in this country by the replacement of liquid milk by dried milk in artificial feeding.

Cow & Gate Milk Food

Cow's Milk made safe and suitable for Baby.

The pre-eminence of 'Cow & Gate' in this respect has been testified to in a recent official investigation, as the following abstract will illustrate :—

> *"This milk is of good quality and content. It is more conveniently stored than fresh milk, and more easily preserved from contamination. Its use for artificially-fed infants has probably not only maintained and improved the general nutrition, but has also directly prevented much gastro-intestinal disease which is so often caused by impure and stale milk."*

In the general nutrition of normal infants, as well as in the prevention of infantile gastro-intestinal disease, the unique success of 'Cow & Gate' has been attributed to the infinite care taken in the selection of the milk used, to the highly scientific control exercised throughout its manufacture, to its standardised and unvarying composition, to its high biological value, and to its bacteriological purity.

The makers will gladly supply samples for clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

'Byno'
Trade Mark

Hypophosphites

An efficient Digestive, Tonic and Restorative

Invaluable in retarded convalescence and asthenic conditions generally

In 'Byno' Hypophosphites are combined the tonic qualities of the Nux Vomica and Cinchona alkaloids, the restorative value of the mineral hypophosphites, and the nutritive and digestive powers of 'Bynin' Liquid Malt which is the basis of the preparation.

'Byno' Hypophosphites has for long been prescribed with great success in convalescence after acute infections and following surgical operations; in nervous and mental conditions due to overstrain or exhaustion; as an adjunct in the treatment of tuberculosis; in asthenia of the aged and in a diversity of conditions where a general tonic and digestive is indicated.

In bottles at 3/6, 6/6 and 12/-

COMPOSITION:

Calcium Hypophosphite	7 gr.
Potassium	2 „
Sodium	2 „
Iron	¼ „
Manganese	¼ „

COMPOSITION:

Cinchona Alkaloids ...	1½ gr.
Nux Vomica Alkaloids (equal to Strychnine)	1/10 „
'Bynin' Liquid Malt ...	1 oz.

Milk Intolerance.

For many years Benger's Food, as is well known, has been used by practitioners throughout the world as a routine diet in all gastric cases, debility, and in cases of milk intolerance. The reason for this may be briefly stated:—

Benger's Food is a special wheaten flour preparation containing, in suitable amount, the two natural digestive principles — Amylopsin and Trypsin — in a latent state.

It is devised and expressly intended to be used in conjunction with fresh cows' milk, or diluted milk, if desired.

The two enzymes are in such condition as to exert their digestive powers under the condition which obtains during the preparation for use.

The Amylopsin acts on the carbohydrates (Starch) of the Food and gradually changes it into soluble sugars (Dextrins and Maltose mainly, with a little Dextrose) more or less according to the length of time allowed for digestion.

The Trypsin acts on the gluten of the flour and on the proteins (Casein, etc.) of the milk so that the curd which forms is softened, and as a result it separates in the stomach in fine readily-digestible flocculi instead of large, often indigestible curds. The extent of digestion can be varied; *it is important to note that complete pre-digestion can never take place.*

Benger's Food contains no preservatives. It is palatable and is free from rough irritant particles.

These considerations show that Benger's Food is not merely a mechanical milk modifier — it is a real modifier of a peculiar character.

THE "LANCET"
describes it as "Mr. Benger's admirable preparation."

A Physician's sample will be sent post free to any member of the Medical Profession making application to the Proprietors:—

FELAMINE

BRAND

SANDOZ

Felamine, an association of the most powerful cholagogue — pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, provides a rational and effective treatment of biliary lithiasis, cholangitis, hepatitis, icterus, and all the symptoms of biliary insufficiency.

Felamine contains no accessory drugs. The cholagogic active principle (cholic acid) is present in an absolutely pure state, free from useless and harmful bile substances.

Indications.

Cholangitis, Cholecystitis, Hepatic Insufficiency, Hepatic Congestion, Jaundice, Chronic Constipation.

Felamine is supplied in Bottles of 50 and 250 Tablets at **5/-** *and* **20/-**

Observations ON THE MECHANISM OF ABDOMINAL PAIN.*

BY

CHARLES H. MAYO, M.D., D.Sc., LL.D.,
HON. F.R.C.S.,
SURGEON, ST. MARY'S HOSPITAL, ROCHESTER, MINNESOTA, U.S.A.

THE subject of abdominal pain is a most interesting and extensive one, and one which may be discussed from many points of view. The work on the nervous system is one of the glories of British physiology. Of late we have come to hear more and more about the involuntary nervous system, so that now the prize-fighter is not the only one who appreciates the importance of the solar plexus. In America our interest in the sympathetic nervous system was greatly stimulated a few years ago by the visit of Royle and Hunter of Australia. Encouraged by their work with spastic leg muscles, a number of surgeons throughout the world have revived the attempts to treat angina pectoris by section of a number of branches of the cervical sympathetic nerve, and are attempting to control hyperacidity and pylorospasm by section of one or more branches of the vagi. These involuntary nerves with their ganglionic hook-ups make me think often of radio apparatus with each tube amplifying the message that is passed. If, however, we do make use of this rather fantastic simile we must think of each ganglion as a group of stations all broadcasting at one time.

There has been much controversy over the nature of the stimulus which produces visceral pain, and Mackenzie and Lennander have actually claimed that pain is felt not in the viscera, but only in the overlying structures. Although some recent studies are tending to revive this view, it is to-day pretty well discarded, and when care is taken to avoid stimulation of nerve-endings in the parietal and visceral peritoneum it can be shown that the structures in the abdomen are sensitive to pulling, clamping, and tying. This is particularly true of the gall-bladder, the urinary bladder, the connective tissue around the pancreas, and the large and small omenta. The fact that the stomach, the intestine, the liver, gall-bladder, pancreas, and spleen appear insensitive to cutting and pinching does not prove that they are incapable of giving rise to pain, because it may be that there is no physiological necessity for these organs to respond painfully to the type of stimulus used.

In general it may be stated that most abdominal pain that is not due to peritoneal involvement is dependent either on undue contraction of a viscus, which brings pressure to bear on nerves in its wall, or on extreme distension, which leads to stretching of the nerves. This would explain the fact that pain is felt during the passage of abnormally intense peristaltic waves, such as those seen sometimes in the colon. That pain may be felt also during relaxation of a peristaltic contraction has been shown by the recent work of Payne and Poulton on the œsophagus. They believe that in a distended muscular tube peristaltic contraction will actually relieve pain if it happens to shorten the length of the muscle and thus relieve tension on stretched nerve-endings.

Kappis has emphasized Meyer's observation that distension of the intestine with gas will produce pain only when the mesentery is stretched and pulled on. Still another explanation for visceral pain may be found in the anæmia of the wall of the intestine when it contracts down so as to resemble a hard white cord. It may be that this can produce the type of pain that is felt in thawing fingers after they have been nearly frozen. Possibly in this case the stimulus is a chemical one—that is, some substance formed in the tissues when they are deprived of oxygen. It should also be noted that the blood vessels are sensitive to pain. Thus puncture of an artery, especially one of the smaller ones, will cause dull pain of a peculiarly unbearable type, and this may be accompanied by reflex sweating and nausea.

Even the solid abdominal viscera appear at times to be sensitive to pain. Thus Foerster noted during the war that while a piece of shrapnel was being removed from the liver of a soldier complaint was made of a painful sensation in the organ. It is well known that the ovary is sensitive to pressure, and the stretching of the tunica albuginea by the growing follicle often produces pain which reaches its maximum just before the structure bursts.

Turning to the anatomical side of the problem, it should be remembered that the parietal peritoneum is innervated mainly by the intercostal nerve, and that the phrenic nerves innervate not only the diaphragm, but also the peritoneum on the under surface of the diaphragm. The sensory fibres in the visceral peritoneum and in the abdominal organs pass back to the spinal cord in association with the sympathetic nerves. The fibres from the stomach, duodenum, cæcum, ascending colon, pancreas, spleen, liver, and gall-bladder return with the greater splanchnic nerves, while those from the distal half of the colon go back through the hypogastric and the pelvic nerves.

That the splanchnic nerve contains pain fibres can readily be demonstrated in either experimental animals or man. Even when general anæsthesia is used any stimulus applied to the nerve is likely to produce reflex movements or actual waking. It is easy to show also that splanchnic anæsthesia, or anæsthesia of the abdominal plexus, will render the whole visceral peritoneum, stomach, duodenum, liver, and gall-bladder quite insensitive to pain.

Langley has stated that the sensory fibres in the splanchnic nerves are white and medullated, and that they rise in posterior root ganglions in the thoracic region of the cord. They pass without interruption to the organs. He and Gaskell believed that the involuntary nervous system proper consists only of connector and effector neurones. The pain-carrying fibres, therefore, do not belong to this system, but are true sensory fibres similar to those found in the rest of the body.

It is very doubtful if the vagus nerves ever have anything to do with the transmission of pain sensations from the abdomen. It was frequently noted during the war that when the upper part of the thoracic portion of the spinal cord was severed by a gunshot wound, peritonitis and other abdominal diseases ran their course without pain. Stimulation of the central end of the cut vagus was shown by Foerster to cause nausea, but not pain.

It has long been known that disease in the gall-bladder or the liver may be accompanied by severe pain in the shoulder and in the side of the neck. This so-called viscero-sensory reflex suggests strongly that the phrenic nerve must have something to do with pain in the upper part of the abdomen, and Ramström has described a branch which unites with the sympathetic fibres of the coeliac plexus to form the phrenic plexus. On the right side these nerves run to a special structure, the phrenic ganglion.

As is well known, the pains of peptic ulcer and of cholecystitis are not always felt in the same place in the epigastrium and back. The site of pain may vary from patient to patient, or from time to time in the same patient. This is not surprising when one remembers how many complicating factors there may be. Cholecystitis in many cases is associated with hepatitis or pancreatitis, and an ulcer near the incisura, or a gall-stone, may produce painful spasm of the pyloric muscle. The perforation of an ulcer into the pancreas or into the lesser peritoneal sac should also change the type and situation of the pain, because another group of sensory nerves then become involved. It is conceivable also that differences in the anatomical distribution and course of nerves in different persons might cause differences in the distribution of pain produced by ulcer or cholecystitis.

That our knowledge in regard to the mechanism of abdominal pain is still inadequate has been realized many times by surgeons as they have attempted to relieve the gastric crises of tabes. Those crises may perhaps be divided into three groups: (1) those in which pain, vomiting, and hyperalgesia of the abdominal wall are the most prominent symptoms; (2) those in which nausea and vomiting predominate, and in which there may also be pain in the larynx, ear, and heart, and perhaps bradycardia; and (3) those in which there is, in addition to the abdominal pain, hiccup; and pain over one or both

[35891

* Made in opening a discussion at a joint meeting of the Sections of Surgery and Physiology and Biochemistry at the Annual Meeting of the British Medical Association, Manchester, 1929.

shoulders. In the first group we suspect that the splanchnic nerves are mainly at fault; in the second we suspect the vagi; and in the third we feel sure that the phrenic nerves are involved.

In all of these types nothing abnormal can be seen or felt during abdominal exploration. On roentgenographic examination it has been found by Groedel, Lüden, and Carnot and Bruyère that the stomach is unusually active during crises, and that the height of the paroxysm of pain corresponds to the greatest intensity of a contraction. Similar observations were made by Daniélopolu with the help of recording balloons introduced into the stomach.

It is remarkable that denervation of the entire stomach rarely abolishes the crises. Foerster has cut all the posterior roots involved in the nerve supply of the stomach, and has sometimes failed to give relief. This must mean either that sensation is reaching the spinal cord through anterior roots, or else that it is arising in some part of the cord or brain, whence it is projected into the abdomen. Actually, in a few cases, after section of the posterior roots had failed to give relief, section of the anterior roots resulted in cessation of pain. In one case the induction of paravertebral anaesthesia, in which the rami communicantes were blocked, was not followed by relief of pain. In another case, after section of the sixth, seventh, eighth, ninth, and tenth thoracic roots had failed to work relief, both vagi were cut below the diaphragm and posterior gastro-enterostomy was performed, but even this extensive denervation failed to influence the severity of the pain.

So far as I know, the phrenic nerves have not yet been cut for the relief of gastric crises. The spinothalamic tracts, which carry sensory impulses up the spinal cord, have been sectioned, and some of the patients so treated have been relieved. It may be possible that the surgeon did not always cut deeply enough, because the fibres from the more cranial segments lie deepest in the cord.

The lesion in tabes dorsalis is in the posterior root gangions and in the dorsal columns of the spinal cord. Gastric crises, however, may be caused by a variety of conditions other than tabes dorsalis. They may be associated with inflammation of the membranes of the spinal cord, injury of the spinal cord from gunshot, or fracture of the spinal column, or they may even result from angioneurotic oedema. Eusterman has described cases of typical gastric crises which were seen in association with duodenal ulcer and angina pectoris. In tumours of the cauda equina the clinical picture may be that of crises involving the bladder, the colon, and the rectum.

I have gone so into detail with regard to tabetic crises because they illustrate how diverse may be the paths through which painful sensations may leave the abdomen and how little we really know about the subject. In some cases one can find zones of cutaneous hyperaesthesia or hyperalgesia. Ever since Head's classical studies it has been known that visceral disease may be accompanied by these zones, and sometimes they are so strictly localized as to indicate the presence of disease in some one of the internal organs. Surgeons know well the tenderness of skin and muscle without rigidity associated with disease of the diaphragm and upper part of the abdomen. They have long recognized also that early pneumonia in the lower lobe of the right lung may simulate appendicitis. I might state, parenthetically, that severe, long-continued pain in a localized abdominal area may be the result of bacterial involvement of the spinal nerve supplying the region and the muscle under it. The source of this infection will usually be found in the mouth, the cervix, or the prostate.

There are certain chronic lesions in the abdomen which produce pain of a type that does not fit well into any of the categories just mentioned. Much has been written about the cause of the pain in gastric and duodenal ulcer. Wilson found that spasm of the duodenal cap and pain occurred simultaneously in twelve out of fourteen cases of duodenal ulcer. Störek found in the bed of a gastric ulcer exposed nerves with neuromatous formations. The pain of gastric ulcer may be compared to the pain of a varicose ulcer of the leg. I believe the exacerbations of pain in these ulcers are the result of vascular spasms and later small extensions in the margin of the lesion. When these little extensions heal, as they do after a week or two, the pain disappears. Certain peptic ulcers do not cause pain, and when pain has been present its disappearance does not necessarily mean that the ulcer is healed.

As compared with the skin, the abdominal viscera contain very few nerve-endings, so fairly large areas in these organs must be insensitive. Although, under local anaesthesia, one can incise the stomach without causing pain, I doubt if this experiment proves that the pain of gastric or duodenal ulcer is any different from that produced by local extension of a varicose ulcer of the leg. It may be, however, that the pain produced by a peptic ulcer is the result of a long-continued summation of stimuli which, if acting singly, would not affect the consciousness of the patient. Actually, Adrian has shown recently with the string galvanometer that a stimulus applied to a single receptor organ will produce a rhythmic disturbance in the nerve, a disturbance which is repeated from five to a hundred times a second. For simple end-organs, such as those which record pain, the duration of the volley of impulses was found to vary directly with the strength of the stimulus; the number of impulses in each second did not vary to any great extent. The significance of this observation lies in the fact that one method of overcoming synaptic resistance (and getting an impulse to reach the field of consciousness) is to keep repeating the message. In the spinal animal this is exemplified by the summation of inadequate stimuli, which finally results in, let us say, the scratching response. In cases of gastric ulcer, therefore, it may well be that it is the long-continued summation of inadequate stimuli that eventually produces pain.

Experience is invaluable, and yet, now that we are being helped so much by the roentgenologist and the laboratory worker, we must not forget that two or three decades ago pain was often a misleading as well as a leading symptom. What is needed is mass accumulation of data for careful analysis. I believe with Ryle that we need more knowledge concerning abdominal sensations, that we may more carefully elicit and interpret symptoms of disease in an earlier stage—in fact, anticipate and possibly prevent the advance of disease. With the abdomen open the surgeon, by splanchnic injection of anaesthetic solutions, frees the whole abdomen of pain, and yet local anaesthesia in the abdomen is secured by injecting, within peritoneal folds, the lesser or greater omentum or local mesenteric areas, and this is often an advantage over general anaesthesia.

I think I have said enough to convince you that when the character and site of an abdominal pain tells something to the surgeon, it does so not because he knows much about the underlying anatomy and physiology, but because he has noted that particular pain many times before, and he remembers what he found when he opened the abdomen.

ABDOMINAL PAIN.*

BY

SIR E. FARQUHAR BUZZARD, BT., K.C.V.O., M.D., F.R.C.P.,

REGIUS PROFESSOR OF MEDICINE, UNIVERSITY OF OXFORD; CONSULTING PHYSICIAN, ST. THOMAS'S HOSPITAL.

As one of the individuals deputed to open this discussion on abdominal pain I warmly appreciate the honour, greedily claim the privileges, and reluctantly assume the responsibilities of the task. The honour is great in direct proportion to the names of those who precede and follow me, and in this instance, therefore, is one of high degree. The privileges entitle me not only to a first and last word, but to the choice of any aspect of the subject under discussion on which to base my opening remarks. The responsibilities lie in raising questions and making dogmatic statements such as will invite criticism and provoke attack.

Pain has always played an important part on the stage of human life. In the eyes of the moralist its chief function has been that of a corrective; to the physiologist its interest lies in its influence as a protective agent; to the man of medicine its share in promoting the healing of wounds and in the detection of disease makes its widest appeal.

In this assembly we may expect that more attention will be paid to pain as a noxious stimulus or an aid to diagnosis than as an instrument of punishment. On the other hand, the usefulness and uselessness of physical suffering constitute a theme so large and so full of difficulties and dangers that we may well leave its philosophic consideration out of to-day's programme.

The increment of knowledge which has accumulated during the last fifty years concerning the various functions of the nervous system, and particularly in regard to afferent and reflex mechanisms, has led us to understand much about the origin of pain in all parts of the body, and has encouraged us to look upon and recognize it as a valuable asset for purposes of diagnosis. We have learned that the threshold of pain, under normal conditions, is higher than that of other forms of sensation, and, when passed, leads not only to recognition by the higher centres, but to other phenomena which are more or less outside the control of the will. Urgent motor responses, such as the withdrawal of the leg when a noxious stimulus is applied to the sole of the foot, or the active lacrymal secretion associated with a painful injury to the surface of the eyeball, are familiar examples of such reflex phenomena within the sphere of action of the ordinary spinal and cranial afferent nerves.

On the other hand, the territory of the sympathetic nervous system presents problems which are fundamentally different. Here we are faced by an involuntary musculature which carries on its activities in health without intruding upon consciousness, and by viscera which can be maltreated in many ways without the production of pain. These viscera are protected from outside injury by one line of defence, the abdominal parietes, which reacts to painful stimulation as do other parts of the surface of the body. But many of these viscera are hollow, open to attack from within, and dependent on a special nervous mechanism of their own to maintain their integrity and to preserve their functions. The chief menace to the latter is provided by disease or deformity of the visceral walls, or by the presence of obnoxious and abnormal substances within their cavities.

The abdominal wall is designed to protect the viscera against external trauma or against morbid processes originating in its constituent tissues by means of an afferent and reflex mechanism of the ordinary cerebro-spinal type, with pain, aroused by various familiar stimuli, as its vigilant outpost. The daily experience of frequent attacks, or of threatened attacks, of greater or less seriousness, upon the abdomen, raises this mechanism to a level high enough for discrimination and localization to be added to mere reflex response.

On the other hand, the hollow viscera are provided with a nervous mechanism of sympathetic origin which usually carries on its functions quietly, unobtrusively, and undisturbed by the outside world. Variations from the normal routine are rare events, generally insufficient in degree to produce or necessitate more than passing notice, easily met without any call for help on the organism as a whole, and too trivial to require any special discriminative or topographical recognition on the part of the higher cerebral centres.

But exceptional and untoward events may happen even in this tranquil territory. Obnoxious strangers are introduced or appear from unexpected quarters, and their ejection is not only imperative and urgent, but demands unaccustomed effort and perhaps the help of auxiliary forces. The alarm is signalled through the agency of unusual afferent impulses, the spasmodic efforts of the involuntary musculature of the visceral walls are reinforced by skeletal muscles summoned to its aid, and the clinical picture of colic is evolved. Such, broadly, is the physiological story of a bedside incident familiar to all who practise medicine and surgery.

Pain is the outstanding feature which overshadows all else in this picture, and it is to the origin of this pain that so much research has been directed of recent years. Its indefinite localization, its intermittent paroxysmal character, the effortful and doubled-up attitude it provokes—all serve to proclaim its distinction from the localized, continuous, and immobilizing pain associated with disease of, or injury to, the abdominal wall, including in the latter term the parietal peritoneum.

Splanchnic pain is something very real, at any rate to anyone who has experienced or witnessed the tortures of colic, and yet we know that the abdominal viscera are quite insensitive to ordinary painful stimulation, such as section by knife or piercing by needle. For this reason we may assume an absence of true pain receptors in the visceral walls and attribute the production of pain to stimulation of nerve fibres. This is the more likely in view of its high threshold, its radiative and its non-discriminative characters—features characteristic of the pain resulting from the irritation of spinal nerve fibres in other parts of the body. There is a good deal of evidence to show that stretching the visceral tissues can provoke pain, and there can be little doubt that most examples of splanchnic pain are associated with unusual motor activity or muscular spasm. More speculative, however, must be any hypothesis attempting to describe exactly the form of stimulus which provokes pain and the precise nervous structures on which it acts.

Another question, too, awaits a clear answer, and that is the order of events which give rise to pain. Take, for instance, the case of a small calculus impacted in a ureter and attacks of colicky pain at long intervals. What initiates at any particular moment the paroxysms of pain referred at first to the penis and spreading all over the lower part of the abdomen? Is the afferent impulse which arouses the muscular spasm in the wall of the ureter a painful impulse, or is the pain only evoked by the raising of tension consequent on the muscular spasm?

Finally, we would welcome a clearer insight into the variations which, it seems, must occur in the threshold of painful sensibility under conditions of health and disease. Damage or disease of superficial tissues in the territory of spinal nerves will undoubtedly lower their threshold of pain, and it may be justifiably inferred that ulceration within a hollow viscus may bring about a similar result. Of particular interest from a clinical point of view is the length of time during which a lowering of the pain threshold may persist after a structural abnormality has been removed or all evidence of its presence has disappeared. An answer to this question might throw much light on the problem of certain chronic abdominal cases which are alike the despair and the livelihood of surgeons. We are inclined to attribute the hypersensibility of such patients to some alteration of mental attitude, to hide our ignorance behind a diagnosis of psychalgia or functional pain, always casting suspicion on the higher levels of the nervous system. This may be an

* Read in opening a discussion at a joint meeting of the Sections of Surgery and Physiology and Biochemistry at the Annual Meeting of the British Medical Association, Manchester, 1929.

unfair interpretation of symptoms which are difficult to understand, and we might consider the possibility of deranged function at a lower level—a sympathetic level—being responsible for a threshold of pain so depressed as to make many stimuli, innocuous under healthy conditions, assume noxious habits and qualities.

There is some support for such a view to be obtained on the clinical side. The patient who develops chronic abdominal pain after an abdominal operation, and who is prepared to undergo a relay of further operations for its relief, is often not of the neurotic type in the first instance. She does not respond to, or rather does not recover under, psychotherapy. Time, uninterrupted by much medical or any surgical treatment, may bring about complete recovery, unless fear and impatience combine to produce a psychoneurosis. After all, we are familiar with localized areas of hyperaesthesia in the distribution of the peripheral nerves after injury or sepsis, areas which may be exquisitely sensitive to all stimulation for months and years, and which may yet gradually approach a more normal condition if left well alone.

On the other hand, painful intestinal spasm of a paroxysmal type is a somewhat rare but very definite symptom in anxiety states, and may give rise to much difficulty in diagnosis, as well as to needless laparotomy. Such instances as I have met with have occurred in profoundly neuropathic patients, and have only yielded to psychotherapeutic measures. They are interesting from a physiological standpoint because they are examples of severe colic without any discernible local lesion. The intense pain and resulting tenderness, sometimes accompanied by a palpable knuckle of contracted gut resembling what can be felt in a cramp of a skeletal muscle, strongly suggest that splanchnic pain is chiefly due to muscular spasm, and may be independent of any morbid process either in the intestinal wall or in the bowel contents. Whether the pain is the result of pressure exerted on the intrinsic nervous structures, or due to interference with their blood supply, is a question which has yet to be answered. The early intermittent colicky pains associated with mesenteric thrombosis and embolism bring the circulatory condition into prominence as a causative factor.

There is perhaps no more important and difficult problem confronting a surgeon than the interpretation of pain in acute abdominal conditions, but, having referred to some of the features which characterize the splanchnic and peritoneal types, I shall leave their further elaboration to those who are much better qualified to deal with them than I am. In particular, we may hope to hear Mr. Morley giving us the result of his carefully considered research into the nature and meaning of the pain associated with appendicitis. Meanwhile, may I recall to your memory some of the heteronomous types of abdominal pain which are liable to entrap surgeon and physician alike?

First of all, there is the immobile painful abdomen met with in acute pulmonary disease—in pneumonia and infarct of the lower lobes, for instance. This is sufficiently common, and has been so long recognized that it deserves no more than a passing reference. Less common is the *acute* epigastric pain associated with vomiting and profound collapse observed in cases of coronary thrombosis, and generally found in persons suffering from arterial degeneration. It may simulate the picture of a perforated gastric ulcer so faithfully as to be a real diagnostic pitfall. Still more rare are the attacks of severe abdominal pain, colicky in type, which result from atheroma of the abdominal aorta and which have earned the title of "angina abdominalis." They resemble their cardiac namesakes in being *paroxysmal*, often at long intervals, and do not present associated physical signs such as should justify an exploratory laparotomy.

The gastric crises of tabes have an unpleasant notoriety for creating an atmosphere of diagnostic doubt, and the problem is generally dismissed in textbooks with the statement that the presence or absence of knee-jerks will *suffice* for its solution. As a matter of fact, the presence or absence of knee-jerks *may* guide us to the presence or absence of the tabetic process at the *lumbar level* of the cord, but has no bearing on the presence or absence of a lesion of the *upper dorsal* roots. On the other hand, the pains of tabes, although pathogenetically obscure, are clinically characteristic, and those which infest the epigastrium present much the same features as those which inflict torture on the patients' limbs. They are lancinating, rapidly repeated, and chronologically paroxysmal. They are associated with intense superficial hyperaesthesia, but with no such muscular immobility or rigidity as is met with in peritonitis. The accompanying nausea and vomiting may be regarded as secondary and reflex in origin. In fact, careful attention to descriptive details and to the abdominal physical signs should serve to distinguish gastric crises from any morbid process originating in the abdominal organs without the necessity of worrying the patellar tendons.

Those who follow me will discuss the views held and supported by various authorities during the last forty or fifty years in regard to the origin and nature of abdominal pain. Since Ross advocated the distinction between splanchnic and somatic pain there have been many workers in this field of research. Mackenzie, Head, Hurst, Ryle, Payne and Poulton, Maylard and Bolton have all contributed much of value towards the solution of a very important and difficult problem from the clinical standpoint, and we may hope that its ventilation in a physiological atmosphere to-day may lead to its further elucidation.

Whether or not this hope is fulfilled, the discussion may be welcomed as evidence that the profession is taking an increasing interest in the meaning of pain, is more inclined to subject pain to careful analysis, and is more appreciative of the position of pain in the proper execution of its daily work. We may look forward with confidence to a time when the loose employment of such terms as rheumatic, neuritic, neuralgic, etc., for descriptive purposes is abandoned, and when due regard is paid, not only to the site and quantity, but also to the precise quality of pain as an essential factor in the diagnosis of disease.

As Hilton wrote sixty-five years ago: "Every pain has its distinct and pregnant signification, if we will but carefully search for it."

CONDITIONS SIMULATING PULMONARY TUBERCULOSIS;

WITH SPECIAL REFERENCE TO PNEUMONOCONIOSIS AND BRONCHIECTASIS.*

BY

F. G. CHANDLER, M.D., F.R.C.P.,

PHYSICIAN WITH CHARGE OF OUT-PATIENTS, CHARING CROSS HOSPITAL; PHYSICIAN, CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK, E.

THE substance of what I am about to say might be crystallized in one sentence: It is by bacteriological examinations of the sputum and faeces, and by these examinations almost alone, that we can establish a diagnosis of pulmonary tuberculosis or exclude it. I know that there are exceptions, such as the very early, sometimes the *miliary* and the latent case, and even occasionally, but very rarely, in other instances, but in the vast majority of cases the dogma will be found true. It is because of the neglect of this simple test that a great many cases of pulmonary tuberculosis escape recognition in the early stages. It is because of this neglect that many non-tuberculous conditions are diagnosed as tuberculous, and their true nature is unrecognized. If tubercle bacilli are not found after repeated examinations of the sputum, and a few examinations of the faeces, and there are definite signs and symptoms, it is certainly the time to begin to consider that the condition may be a non-tuberculous one.

Some may ask why I insist so strongly on the examination of the faeces, and an explanation still appears to be necessary. In many cases of active pulmonary tuberculosis either no expectoration is produced or what is produced is merely mucus or muco-pus from the nasopharynx. This is specially apt to occur in children and

* A paper read in opening a discussion in the Section of Tuberculosis at the Annual Meeting of the British Medical Association, Manchester, 1929.

women. All the pulmonary secretion is swallowed. Millions of tubercle bacilli may be swallowed in this way, and may easily be found in the stools by the antiformin method of examination. Such bacilli, when tuberculous food or milk is excluded, imply pulmonary tuberculosis, for a primary tuberculous enteritis is a pathological curiosity, and there is no other origin of the bacilli. The existence of these bacilli has been known for some time, but the test was not a routine one in most clinics. In 1924 I made, with my house-physician Dr. Stobo, an investigation into the quesyphilitic infection, and the presence of tubercle bacilli, was of real practical clinical value. We found it of the greatest value, and since then we have made it a routine test at Victoria Park, when the sputum fails us. The controls had no tubercle bacilli in the faeces. Subsequent experience has fully confirmed the importance of this examination.

There are a great many conditions which may simulate pulmonary tuberculosis, sometimes only when they are fairly advanced as with pneumonoconiosis, sometimes only at the beginning when symptoms may be similar or identical—for instance, cough, sputum, haemorrhage—later they begin to diverge and the picture in each case becomes distinctive—as, for example, bronchiectasis. Occasionally tuberculosis may coexist with one of the diseases by which it is simulated, which may cause great difficulty for a time. The knowledge that such conditions may be present concurrently will help us to arrive at the correct dual diagnosis. I will enumerate the more common of these apparently fortuitously associated affections. I say apparently fortuitous, for so it seems to be, except in the case of certain forms of pneumonoconiosis, where silica increases the liability to tuberculous infection.

1. *Pneumonoconiosis and pulmonary tuberculosis.*
2. Lymphadenoma and pulmonary tuberculosis.
3. Syphilis and pulmonary tuberculosis.
4. New growth and pulmonary tuberculosis.
5. Bronchiectasis and pulmonary tuberculosis.
6. *Mitral stenosis and pulmonary tuberculosis.*

The following points will help in the diagnosis. In each case it is assumed that tubercle bacilli have been found.

1. *Pneumonoconiosis and Pulmonary Tuberculosis.*—Here the history of the patient's employment would help. The other distinctive points will be discussed later.

2. *Lymphadenoma and Pulmonary Tuberculosis.*—This may cause great difficulty, but a gland may be available for examination, though this unfortunately is not always histologically distinctive. Curious intermittent exacerbations of temperature may suggest lymphadenoma. The *x*-ray picture may show enlarged glands or masses in the mediastinum. If there is a large pleural effusion obscuring the *x*-ray picture, replacement of the fluid by oxygen or air and subsequent radiography may reveal the presence in the mediastinum or lung of large masses characteristic of lymphadenoma or growth, and unlike tuberculosis. The response to arsenic and *x*-ray treatment may help.

3. *Syphilis and Pulmonary Tuberculosis.*—Here a strongly positive Wassermann reaction or a history of previous syphilitic infection, and the presence of tubercle bacilli, will help to establish the dual diagnosis.

4. *New Growth and Pulmonary Tuberculosis.*—This combination may cause great difficulty, but the deterioration of the patient's condition, more rapid than one would expect with the amount of disease present if it were tuberculous, and the presence of radiographic shadows unlike those produced by tubercle, will give rise to a suspicion, which will be confirmed as the case progresses. Sometimes, however, a very dense fibrosis may simulate neoplasm, both in cases of tuberculosis and pneumonoconiosis, but the progress of the case usually gives a clue to the true nature of the affection. We have had many cases at Victoria Park Chest Hospital where tuberculosis and primary malignant growth have coexisted in the lung. In certain cases the *x*-ray picture, in the early stages, is by no means pathognomonic. In such a case under my care certain symptoms were suggestive of either tuberculosis or malignant growth, and at first the diagnosis was not easy. But the absence of tubercle bacilli, the steady deterioration of the patient, and yet so small an area of disease aroused a suspicion of malignant disease, which was confirmed later. If tubercle bacilli had been present at that stage a correct diagnosis would have been problematical. I have known a tuberculous mass to be removed from the lung in the belief that it was a growth. On the contrary, growths in an apparently operable stage may be left, because they are thought to be inflammatory. When the diseases coexist the mistake does not matter so much, as drastic treatment could scarcely be undertaken. But with malignant disease by itself a correct and early diagnosis is important if we hope to employ effective treatment. Although some cases may present great difficulty, the absence of tubercle bacilli, the symptoms, and the *x*-ray picture will usually provide sufficient evidence on which to diagnose malignant neoplasm of the lung. Paralysis of one of the phrenic nerves or of one of the recurrent laryngeal nerves is strong evidence in favour of growth and against tuberculosis.

5. *Bronchiectasis and Pulmonary Tuberculosis.*—The diagnosis of bronchiectasis will be discussed in more detail later. With modern methods of diagnosis the coexistence of these two conditions can be demonstrated almost with certainty.

6. *Mitral Stenosis and Pulmonary Tuberculosis.*—The haemorrhages which may occur in mitral stenosis may simulate tuberculosis, but the characteristic signs of a mitral lesion with tubercle bacilli in the sputum usually make the diagnosis easy. The physical signs may be of no help. The *x*-ray picture may be characteristic of tuberculosis, but the presence of infarction, and the denser striations of pulmonary engorgement, may make the picture equivocal, and therefore reliance must not be placed on the *x*-ray findings alone.

The conditions which may simulate pulmonary tuberculosis may resemble it because of symptoms such as continuous fever, or wasting, or haemorrhage, or because of signs such as those of fibrosis, or because of the appearance of a serous pleural effusion. It would be far too long a task to discuss in detail the differential diagnosis of every one. I must content myself, therefore, with enumerating the various diseases, giving here and there an impressionist hint at the most important points in their differentiation, and dealing in fuller detail with those with which we are most likely to be confronted, with especial reference to pneumonoconiosis and bronchiectasis.

Serous Effusion.—The causes of a serous effusion, other than tuberculosis, are lymphadenoma, malignant growth (secondary or primary), dermoid, cardiac, or renal disease, subphrenic abscess, polyserositis.

Lymphadenoma I shall refer to again later. *A malignant serous effusion* may be diagnosed by replacement and thoracoscopy in cases where nothing else will help. Occasionally the *x*-ray picture is distinctive after replacement. In spite of what is often written, the effusion is seldom bloody, and the cytology of the fluid seldom of help. *A dermoid* is usually obvious in the skiagram. With an effusion secondary to *cardiac* or *renal disease* careful examination will, as a rule, show the underlying cause. Sometimes, however, a recurrent unilateral effusion may be cardiac in origin, and it may be difficult to say whether it is tuberculous, malignant, cardiac, or due to polyserositis. I have seen a case of serous effusion above a subphrenic abscess called tuberculous. But there was no excuse for the mistake, for there was a high leucocytosis and daily rigors, and the latter never occur in tuberculosis.

In *polyserositis* there may be associated changes, mediastino-pericarditis, ascites, perihepatitis, and perisplenitis, with enlargement of the liver and spleen. The effusion, however, may be an isolated phenomenon, and the diagnosis will only be made after many aspirations, the fluid tending ever to recur while the patient's general condition deteriorates surprisingly little.

Many cases of long-continued fever without physical signs may arouse a suspicion of tuberculosis. If the patient is seriously ill miliary tuberculosis may be suspected. Repeated *x*-ray examinations of the chest may reveal quite definitely the evolution of miliary tuberculosis in the lungs. This may be illustrated by three slides. The first shows widely distributed small opaque dots. The second shows an increase in size of these shadows. The third shows a spontaneous pneumothorax to have occurred, while the

lungs are becoming more and more grossly involved. The diagnosis was confirmed at post-mortem examination.

In every case of obscure fever it is important first to exclude a *Bacillus coli* infection of the urinary tract and those diseases that may be diagnosed by blood examinations and agglutination reactions—as, for example, the typhoids, malaria, and even rat-bite fever, Malta fever, and *Bacillus abortus* fever. With the last-mentioned rigors are a feature, and these, as I have already remarked, never occur in tuberculosis.

Subacute bacterial endocarditis may be extremely difficult to diagnose. Blood cultures, which should always be performed, are frequently disappointing. The most important diagnostic point, in my opinion, is the occurrence of embolic phenomena in the skin, the kidneys, the spleen, and elsewhere.

Cryptic collections of pus, as in a subphrenic or perinephritic abscess, will almost invariably give a high leucocytosis, but rare cases of pyonephrosis and carbuncle of the kidney with a blocked ureter may fail to give rise to this leucocytic response and may yield few or no urinary signs, thus making the diagnosis more difficult. Rigors, however, should at once make the diagnosis of pus, somewhere, almost certain. With generalized streptococcal and staphylococcal infections great difficulty may be experienced. Blood cultures and urine cultures may help, but I would utter a warning against accepting, as proof positive, the finding of streptococci and staphylococci in the urine by culture only.

Hyperthyroidism of the type that begins with great wasting and tachycardia, with no other signs or symptoms, may suggest tuberculosis; but the absence of fever, and of tubercle bacilli and physical signs, would almost exclude tuberculosis, for such severe and dramatic symptoms could hardly be due to incipient phthisis. The determination of the basal metabolism would probably suggest hyperthyroidism.

Chronic conditions which may simulate pulmonary tuberculosis owing to signs and symptoms may be tabulated as follows:

1. Unresolved pneumonia, or broncho-pneumonia.
2. Obscure empyema or simple unrecognized empyema.
3. Non-tuberculous fibrosis.
4. Apical catarrh.
5. Pneumonoconiosis.
6. Bronchiectasis.
7. Lung abscess.
8. Neoplasm (malignant or innocent).
9. Fungus Infections: Actinomycosis. Aspergillosis. Blastomycosis.
10. Spirillosis (or broncho-pulmonary spirochaetosis).
11. Pulmonary distomiasis.
12. Hydatid.
13. Mitral stenosis.
14. Lymphadenoma.
15. Syphilis.
16. Foreign body in bronchus.
17. Bronchial stenosis.

Of these the spirillum, fungus, and fluke infections [illegible] acteriological examination. Before [illegible]r spirochaete as the cause of the conditions must be satisfied. The spirillum must be constantly present, present in large numbers, and the sputum must contain the organism in numbers far in excess of those found in the saliva. Such a differential examination should therefore always be made. A massive basal tuberculosis may simulate unresolved pneumonia, especially when the condition has apparently followed an acute influenzal attack. The condition of the patient, the absence of leucocytosis, the presence of tubercle bacilli, are the diagnostic points.

Certain cases of *obscure empyema* may cause difficulty, but the history, the leucocyte count, the *x*-ray examination, skilful exploration, and even exploratory thoracotomy, will usually give the clue. From time to time cases of chronic empyema that have been treated as tuberculosis are admitted to hospital. This mistake is usually unpardonable, and is mostly due to ignoring the history of onset.

The only method that I know of distinguishing *a non-tuberculous from a tuberculous fibrosis* is by the presence or absence of the tubercle bacillus. If tubercle bacilli are present it is a tuberculous fibrosis, if absent it is a non-tuberculous fibrosis, except of course in completely healed extensive tuberculosis or after the cessation of artificial pneumothorax treatment, when tubercle bacilli had previously been found.

Apical Catarrh.

There is no doubt, I think, that after certain catarrhal conditions of the lung, especially after influenza, constant crepitations may be heard at the apices which may persist for some time. They naturally suggest the possibility of tuberculosis. I have investigated many such cases, and have come to the conclusion that a simple catarrh, possibly associated with adhesions, explained the signs. The only way to be certain is to follow the usual routine of evening temperature record, weight record, sputum examinations, and possibly an *x*-ray examination. In some epidemics, however, this phenomenon will be found so frequently that we are probably compelled to use our judgement as to which cases require the complete investigation.

Pneumonoconiosis.

This condition may arise from many occupations. Thus we get anthracosis, silicosis, or chalicosis, siderosis, asbestosis, byssinosis (workers in cotton, felt, and shoddy mills). In most cases, however, the trouble is due to silica.

Symptoms.—Of 36 cases of silicosis analysed by Drs. Sutherland and Bryson,[1] seventeen had no symptoms. In other cases the symptoms were almost entirely shortness of breath, cough, and expectoration. There was no instance of haemoptysis. Wasting was not usual. In some of the cases of asbestosis that we have investigated at Victoria Park Hospital, however, there has been extreme wasting and easily produced cyanosis on exertion, or on contracting a cold, etc.; but perhaps the most remarkable symptom is the dyspnoea. Many cases of asbestosis have been collected recently by Dr. W. Burton Wood, who has made a valuable contribution to the subject in the May issue of *Tubercle*.

The diagnostic points are the history, the symptoms, the physical signs, the absence of tubercle bacilli, the *x*-ray picture, and, in some cases of asbestosis, the finding of asbestos fibres in the sputum, described by Dr. S. Roodhouse Gloyne in the June issue of *Tubercle*, or, as pointed out by Dr. M. J. Stewart, the discovery of yellow club-shaped "curious bodies" which had previously been demonstrated in lung sections. Lung puncture has also been tried, but I personally do not consider this justifiable.

The physical signs may be simply those of a delicate fibrosis or perhaps emphysema. Later there may be contraction of the chest wall and dullness to percussion. Gross fibrosis may occur. The adventitious sounds are like those of any other type of fibrosis.

The *x*-ray picture differs according to the stage of the disease and the type of dust—for example, gold miners' lungs, potters' lungs, and asbestos lungs may all give a different appearance. Help has been claimed from the localization of the abnormal shadows, but these cannot be regarded as pathognomonic; the appearance may simulate tuberculosis, any sort of fibrosis, or even new growth of the lung. On the other hand, we occasionally get skiagrams which reveal an unexpected widespread fibrosis throughout the lungs in cases in which there is no history of exposure to dust.

Where the condition is established, however, there will be little difficulty in diagnosing the condition from the *x*-ray picture, the history of the case, and the absence of tubercle bacilli. The distribution of the fibrosis is suggestive—for example, its rough symmetry, its selection of the mid zone. In the early stages diagnosis may be most difficult, and it is only the history of the patient's occupation, the dyspnoea, and perhaps the *x*-ray picture, on which a diagnosis may be based.

Bronchiectasis.

A few years ago the differential diagnosis between bronchiectasis, pulmonary tuberculosis, and other diseases was by no means easy. In the advanced stage, of course, there was little difficulty, though even here serious mistakes could be made—for example, abscess, chronic empyema, or foreign body in the bronchus might be called bronchiectasis—but in the early stages of the evolution of the

[1] Report on the Occurrence of Silicosis among Sandstone Workers. H.M. Stationery Office.

disease, stages which can extend over very many years, a diagnosis was often difficult or impossible. At such a time I should have been compelled to talk at length about symptoms and signs, and at the end have left matters as they were—uncertain. We might hazard a shrewd guess, but it would have been an opinion, not an established fact. Now, owing to the introduction of iodized oil by Sicard and Forestier, we can claim to prove or exclude bronchiectasis and to localize it. The symptoms at first may be identical with those of tuberculosis—cough, sputum, haemorrhage; the physical signs do not really help, for tuberculosis may be basal, and bronchiectasis apical. The *x*-ray picture of both diseases may be similar, or in both cases may show nothing distinctive. If, therefore, with such symptoms there is an absence of tubercle bacilli in the sputum and faeces, a non-tuberculous condition should be thought of, iodized oil should be given, and the diagnosis established. I must confess, however, that in one or two cases I have been a little puzzled to determine whether the cavities revealed were tuberculous or bronchiectatic. In the example shown, however, I think it will be agreed that the appearance is that of lung cavitation rather than dilatation of bronchi.

In chronic *lung abscess* there are no tubercle bacilli. The *x*-ray appearance is suggestive. Lipiodol, as a rule, does not enter the affected area, thus differentiating it from bronchiectasis.

Malignant growth has already been discussed. *Innocent tumours*, as a rule, have a distinctive appearance on the skiagram. One great pitfall is to mistake lymphadenoma for an innocent tumour, but to discuss this would be to digress too far beyond the limits of my subject.

Lymphadenoma may simulate pulmonary tuberculosis in many ways—by long-continued fever, by lung symptoms and signs, by the production of a pleural effusion. It is one of the most difficult of all causes of obscure fever, but the pattern of the temperature chart, the curious intermittent regular bouts of fever, will frequently help. If primary in the chest, the bulk of the disease is probably in the mediastinum, and will so appear in the skiagram. If an effusion is present and there is doubt of the diagnosis, replacement by gas and subsequent radiography will probably reveal masses in the mediastinum, perhaps extending into the lung. The response to treatment by arsenic and *x* rays may be a further help in diagnosis.

Syphilis.—Although many different syphilitic affections of the lung are described, such as massive consolidation, chronic bronchitis, bronchiectasis, etc., the only certain syphilitic conditions that I have seen are an apparent gumma in the lung, a gummatous mass in the mediastinum causing venous obstruction, bronchial stenosis, and the changes following pressure by an aneurysm. The history, the Wassermann reaction, the *x*-ray picture, and the response to treatment may give the diagnosis.

With *foreign body* in the bronchus, the history and bronchoscopic examinations are the most important points. In *bronchial stenosis* lipiodol injections and bronchoscopic examinations are essential.

To sum up, in difficult cases the routine to pursue will be as follows: A careful history, an exhaustive bacteriological investigation, lipiodol injections, *x*-ray examinations, and bronchoscopic examinations. In certain cases such procedures as replacement and thoracoscopy will be needed, in others even an exploratory thoracotomy. Of all these I would put first the bacteriological investigation.

SOME PHARMACOLOGICAL ASPECTS OF AVERTIN.

BY

F. B. PARSONS, M.B., M.R.C.P.

(From the Pharmacological Laboratory, Cambridge.)

ANY recent advances which have been made in anaesthesia have been rather those of improved methods of administration and technique than the introduction of new anaesthetics. This is due partly to the fact that anaesthetics have come to be regarded as substances to be administered by inhalation, a method which has attained popularity because it permits accurate control and regulation of the duration and depth of anaesthesia; and partly to the reliability of three volatile drugs—ether, chloroform, and nitrous oxide—introduced in the very earliest days.

The rectal administration of anaesthetics does not permit of such fine control of anaesthesia as can be obtained by inhalation. Gwathmey[9] has shown that anaesthesia results when ether is absorbed at a constant rate from a solution in olive oil given by the rectum, and that the drug is excreted by the lungs. Obviously such considerations do not apply to non-volatile anaesthetics. Rectal anaesthesia has certain practical advantages: it is more comfortable for the patient, it does not necessarily require the presence of an anaesthetist, for the surgeon himself can administer the anaesthetic, and it is more convenient for operations about the head and neck. The main disadvantages are the risk of irritation to the intestinal mucosa and the difficulty of maintaining a constant concentration of the anaesthetic in the tissues. This second problem is intimately connected with the absorption and excretion of the drug in question, for the administration of a rectal anaesthetic is not continuous, and, once given, it is impossible to control its action further.

Some three years ago it was discovered that tribromethyl-alcohol, a simple organic compound of bromine, possessed the property of producing anaesthesia. Moreover, it has been found[14] that the therapeutic margin of safety is greatest with this substance when it is administered by the rectum. A quantity of experimental and clinical data has been accumulated ([1–7 10 12 13 14 17–23], and others) regarding this substance, which is now issued under the trade name of "avertin." The opinion has been formed that the drug represents a definite advance towards the ideal anaesthetic, largely because of the simplicity of its administration. All that is necessary is to give a definite proportion of the drug per unit of body weight in aqueous solution by the rectum. Administration is not continuous, for, once the requisite quantity of the drug has been injected, the patient becomes anaesthetized and remains so for a period depending upon the amount of avertin given. The drug is absorbed with extreme rapidity,[21] so that, when the operation is over, it is useless to attempt to remove any which may remain in the rectum, as is the case with other rectal anaesthetics.

The pharmacology of avertin has been studied mainly in Germany, and no experimental investigations have been recorded in this country as yet. The present paper includes the main results of an investigation on these lines to confirm and extend previous observations.

Some Physical and Chemical Considerations.

Avertin is an odourless, white, crystalline powder. It has a melting point of 80° C., and is soluble in water to the extent of 3 per cent. at 37° C. Solution occurs very slowly; it takes upwards of forty-five minutes, aided by vigorous shaking, to produce a clear solution. As the solution must be freshly prepared for each anaesthesia this is a material disadvantage, and the makers have to some extent solved the difficulty by issuing the substance dissolved in amylene hydrate, itself a rectal anaesthetic, in the proportion of 1 gram of avertin in 1 c.cm. of the solvent. This solution is readily soluble in water, and avertin can thus be prepared conveniently for rectal injection.

The chloroform/water distribution coefficient of avertin is comparable with that of ether, and indicates that the two drugs have a similar anaesthetizing power. Avertin contains a high proportion, approximately five-sixths, of bromine. In aqueous solutions it is decomposed by heating above 50° C. into hydrobromic acid and dibrom-acetaldehyde:

$$CBr_3.CH_2OH - HBr = CBr_2 : CHOH = CHBr_2.CHO.$$

Many of the earlier difficulties in the use of avertin by rectal administration were due to the presence of these decomposition products. It has been found that they are

markedly irritant to the intestinal mucosa; if a decomposed solution is injected into a cat's rectum an acute haemorrhagic proctitis results within a very short time. The solution should only be used when freshly prepared; and before injection it must be tested for its reaction by adding two drops of a 1 in 1,000 solution of Congo red to 5 c.cm. of avertin solution. If the reaction is less than $pH = 4.5$ the indicator gives a purplish or blue colour and the solution is not satisfactory for use. Although reports

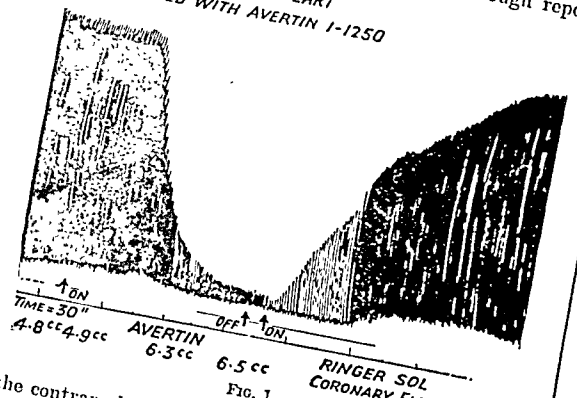

FIG. 1.

to the contrary have been made, I have found that avertin does not decompose readily when exposed to light and air at room temperatures. Solutions have been kept for over three months under these conditions without any evidence of decomposition.

Avertin was first prepared by the action of yeast upon bromal.[25] Since then improved manufacturing methods, based upon the reduction of bromal, have been introduced. There is a close relationship chemically between bromal and chloral; and, further, this holds good up to a point with regard to their decomposition in the body. Chloral circulates in the blood as trichlorethylalcohol, which is excreted in the urine in combination with glycuronic acid as urochloralic acid. Bromal, upon reduction, is converted into tribromethylalcohol (avertin), and it has been suggested[22] that this substance is excreted in the urine in combination with glycuronic acid as urobromalic acid. This is discussed fully later.

The Cardio-vascular System.

The action of avertin upon the heart and blood vessels has been studied by Straub[21 22 23] and Skvortsov;[19] their results have been confirmed and extended in the present research by experiments upon intact animals.

Perfusion of the isolated rabbit's heart with a 1 in 5,000 solution of avertin causes a slight increase, followed immediately by an appreciable diminution, in the force of the heart beat, accompanied by slowing of the rate. These effects are more marked when a 1 in 2,500 solution is used, and with a strength of 1 in 1,250 (Fig. 1) there is no initial stimulation and the beat is almost stopped, but regains its normal amplitude rapidly upon perfusion with this strength of avertin causes arrest of the heart in systole within five minutes.

The coronary outflow is increased in all dilutions of avertin, but particularly at 1 in 2,500, when the increase may amount to 40 per cent. of the flow. Avertin therefore dilates the coronary arteries to a considerable degree.

The intravenous injection of a small dose of avertin (1 c.cm. of a 2 per cent. solution) into a cat already anaesthetized with this drug weakens and slows the heart beat and causes slight cardiac dilatation. The blood pressure falls about 30 mm. of mercury and may remain low for some time. This effect is due entirely to the cardiac action; intestinal volume and limb volume experiments show that the peripheral vessels constrict, but this is not sufficient to maintain the blood pressure at a normal level. A normal anaesthetic dose of avertin administered per rectum has little or no effect upon the blood pressure in the cat, which remains at about 110 mm. of mercury. If the anaesthetic dose of avertin given in this way or subcutaneously is doubled, the blood pressure falls to about 80 mm.; and if it is tripled, it falls to about 50 mm. of mercury. Similar results are obtained with rabbits. These results confirm the findings of Blomfield and Shipway in man,[2] that "there is a slight fall of blood pressure, usually about 10 mm. Hg, which is greater in proportion as the strength of the dose is increased."

Avertin resembles chloroform in its action upon the heart, in that it weakens the force and slows the rate of the beat, with resulting cardiac dilatation and a fall in blood pressure. The great distinction between the two drugs is that there is a greater margin of safety with avertin; effects which are produced by chloroform in a dilution of 1 in 20,000 are not produced by avertin until a concentration of 1 in 1,250 is reached. Accordingly, avertin has a comparatively low toxicity upon the cardiac musculature—about one-sixteenth that of chloroform.

Respiration.

Avertin anaesthesia is accompanied by marked slowing of respiration, due in part to diminution of voluntary movement and to absence of reflex activity from the respiratory tract. It is possible that avertin is not responsible for this depression, which occurs after the administration of the normal dose, for the respiratory centre retains all its reflex effects and its response to drugs; thus inhalation of ammonia and injection of hydrocyanic acid still produce both quickening and deepening of respiration, while the stimulation of an afferent nerve, such as the vagus or sciatic, elicits the normal response.

The respiration under deep anaesthesia shows certain peculiarities which can be demonstrated by a rapid tracing of the respiratory movements. Such a tracing (Fig. 2) shows that the animal first takes a normal inspiration, but by five or six extremely short expirations and inspirations. A normal expiration occurs and then the process is repeated.

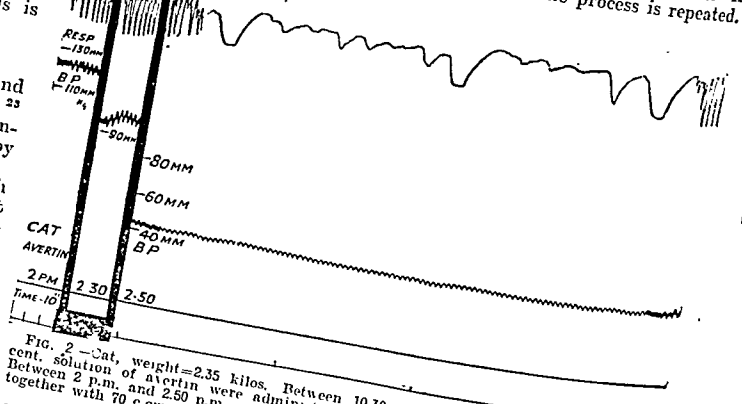

FIG. 2.—Cat, weight=2.35 kilos. Between 10.30 a.m. and 2 p.m., 45 c.cm. of a 2 per cent. solution of avertin were administered per rectum, with resulting anaesthesia. Between 2 p.m. and 2.50 p.m. a further 20 c.cm. of this solution were given per rectum, together with 70 c.cm. subcutaneously.

This type of breathing is strongly suggestive of that described by Lumsden[16] as occurring when the brain is transected through the upper part of the pons; it is known to result from overdosage with anaesthetics. With toxic doses of avertin the respiration becomes slower and more irregular, and finally ceases. Death results from respiratory failure, for the heart continues to beat long after respiration has ceased. Nevertheless, there is a fairly large margin of safety; a cat requires four times the anaesthetic dose administered subcutaneously or per rectum, and very frequently 3 or 4 c.cm. of a 2 per cent. solution intravenously in addition, to cause death from respiratory failure

The Excretion of Avertin.

We are indebted to Straub[21 22 23] for our present knowledge of the excretion of avertin. This writer has established the fact that avertin is excreted entirely in the urine, except for traces in the breath and sweat, and he has expressed the opinion that the drug is excreted in combination with glycuronic acid. My experiments have confirmed certain of his results.

The main difficulty in determining the excretion of bromine-containing anaesthetics is to obtain a simple and accurate method of estimating bromine in the urine. Existing methods, such as those of von Wyss[24] for inorganic bromides only, Hale and Fishman,[11] and Lucas,[15] are unsatisfactory because they involve complex manipulations for separating chlorine from bromine and the use of relatively large amounts of urine, with a resulting undesirable margin of error. In addition, in this work, organic as well as inorganic bromides had to be estimated, and for this purpose von Wyss's method is useless.

With the assistance of Mr. Palmer and Mr. Notton, the following method, depending upon the fixation of organic bromine by sodium carbonate and its subsequent oxidation by iodic acid, was devised. In this way the difficulty of separating chlorine from bromine is overcome, as chlorine is not liberated by iodic acid, except when present in a concentration that is never found in urine.

Method.

The apparatus shown in Fig. 3 was used. It consists of a 300 c.cm. flask, A, with a long neck, B, fitted with a ground-glass stopper, C, carrying a screw-clamp, E. A delivery tube, F, is fused into the neck of the flask as high as possible, and into this is blown a bulb, G, of approximately one inch in diameter. This bulb serves both as a trap and as an inspection chamber for fumes coming over. The delivery tube then passes vertically downwards through a condenser, J, into a boiling tube, H. This is fitted with a cork carrying a small tube, K, which just projects into the boiling tube, while the delivery tube reaches to the bottom. K is connected by rubber tubing to a glass tube, L, dipping to the bottom of a second boiling tube, M. This is also fitted with a small glass tube, N, similar to K.

When bromine is evolved in the flask A and carried over into the boiling tube H, there is no rubber with which it may come in contact. The design of the flask and delivery tube is such that there is no possibility of the contents of the flask splashing into the boiling tube H. Furthermore, by closing the clamp E, fluids in flask A can be boiled at atmospheric pressure. By attaching a pump to tube N boiling point can be reached at a reduced temperature, and by opening clamp E air can be drawn through the apparatus.

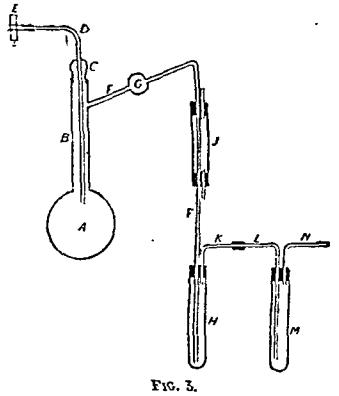

FIG. 3.

A convenient quantity of the urine to be tested is placed in a small nickel crucible; 5 c.cm. was found to be adequate in the case of urines passed immediately following the administration of avertin, but in other cases 10 to 15 c.cm. had to be taken. About 2 grams of solid sodium carbonate are added to the urine in order to fix any organic bromine compounds which otherwise would volatilize, and the whole is evaporated down to dryness.

The crucible, with its contents, is then heated until the organic constituents of the urine are ashed and the sodium carbonate is fused. It is essential that no organic matter be left, because this liberates iodine from iodic acid and interferes with the estimation. After cooling, the fused mass is dissolved in the minimal quantity of N/2 sulphuric acid and is transferred, together with washings of distilled water, to the flask A; 20 c.cm. of N/2 sulphuric acid and 20 c.cm. of an aqueous solution of potassium iodate (7 grams per litre) are added to the flask, and about 15 c.cm. of a 10 per cent. solution of potassium iodide in water are placed in each of the tubes H and M.

The clamp is tightened and the flask is heated. Bromine is liberated by the iodic acid formed by the interaction of sulphuric acid and potassium iodate. The contents of the flask, which at first are colourless, turn brown as the temperature rises. Bromine passes through the delivery tube and bulb into the potassium iodide solution, where iodine is liberated, which dissolves in excess of potassium iodide. Tube M traps any bromine which escapes tube H.

The contents of the flask are allowed to boil until they and the condensed fluid in the trap G are colourless. This takes about twenty minutes, and then air is sucked through the apparatus in order to remove the last traces of bromine from the distillation flask. The contents of the tubes H and M are titrated with a solution of sodium thiosulphate of known strength (1 c.cm. = 0.0008 gram of bromine), using starch as an indicator. The amount of sodium thiosulphate used corresponds with the amount of iodine liberated from the solution of potassium iodide, and indirectly with the amount of bromine liberated from the original material.

Duplicate estimations on urines to which known amounts of potassium bromide and avertin were added showed that 0.2 mg. of bromine could be estimated with an accuracy of 99.8 per cent.

Rate of Excretion of Avertin in Rabbits.

Experiments were made upon rabbits in order to determine the rate of excretion of avertin. Each rabbit was given a dose of avertin subcutaneously, the urine was collected at suitable intervals, and the bromine content estimated. The results obtained are given in Table I.

TABLE I.

	Rabbit 1. Weight 1.8 kg. Avertin given 0.4 g. Bromine content 0.346. No anaesthesia.		*Rabbit 2.* Weight 2.5 kg. Avertin given 0.8 g. Bromine content 0.692. Anaesthesia.

Second day	170	0.0136	60	0.0128		

— = No urine collected.

In the cases of rabbits 1 and 2, estimations were performed until no bromine could be detected in the urine. Rabbits 3, 4, and 5 are included to show the rate of excretion in the first twenty-four hours, and the estimations were not carried further. In the case of rabbit 2, the urine was not collected necessarily each day; upon occasions it was collected for two or three days and then estimated as a whole. Unless otherwise mentioned, the urine was collected at twenty-four hours' interval.

The main points may be summarized as follows:

1. The high figure for total bromine recovery. This was over 98 per cent. in each case in which the estimations were continued until no bromine was found in the urine; this is a much higher figure than that first obtained by Straub,[22] who stated that he could only recover from the urine the equivalent of 81 per cent. of the avertin administered. At the same time, Straub could only find traces of bromine in the sweat and breath of avertinized animals; and the figures obtained here, which allow of the excretion of 1.2 per cent. of bromine by channels other than the urine, confirm this statement. Later, by using an improved technique, Straub[23] asserted that practically the whole of the avertin ingested could be recovered from the urine, thus confirming the figures given in Table I.

2. The amount excreted in the first twenty-four hours. Quantities ranging from 53 to 73 per cent. were recovered in this period. Great caution must therefore be exercised in giving a second dose of avertin before a suitable length of time has elapsed, because an average of 37 per cent. remains in the body twenty-four hours after administration. This shows that avertin is a cumulative drug within certain limits.

3. The period of excretion varies with the dose administered. In the case of the small rabbit No. 1 insufficient avertin was given to produce anaesthesia, and bromine disappeared from the urine on the seventh day. With rabbit No. 2 anaesthesia was produced, and bromine was found in the urine until the sixteenth day. The daily excretion gradually diminished from the first day after administration to a trace on the last few days.

Rate of Excretion of Avertin in Man.

I have had the opportunity, through the kindness of Mr. Arthur Cooke, to study the excretion of avertin in one of his patients. The urine was examined for bromine, with the results shown in Table II. The total bromine

TABLE II.

Man. Weight 9 st. 5½ lb. = 59.5 kilograms.
Avertin given = 5 grams = 4.24 grams of bromine.

	Urine passed. c.cm.	Bromine. Grams.
First day	426	1.43
Second day	852	1.636
Third day	738	0.389
Fourth day	1,136	0.182
Fifth day	738	0.177
Sixth day	824	0.068
Seventh day	—	No bromine
Total bromine recovered		3.882
Total bromine given		4.24
Percentage recovery = 91		

recovery was only 91 per cent., but as a small quantity of avertin solution was lost from the rectum during the operation this figure is probably too low. Excretion was somewhat erratic for the first forty-eight hours, and the amount of bromine passed in the second twenty-four hours exceeded that passed in the first twenty-four hours. This is explained by the fact that the patient experienced considerable difficulty in passing urine in the first twenty-four hours, and reference to the table shows that the quantity of urine passed on the second day was exactly double that passed on the first day; 72 per cent. of the bromine administered was recovered from the urine in the first forty-eight hours, and diminishing quantities were found until the seventh day, when no bromine could be detected.

The Mode of Elimination of Avertin.

It is necessary to remember the analogy between chloral and avertin which has been mentioned previously, and to point out that Straub[22] in his experimental work obtained results which upheld the theoretical contention that avertin is excreted in combination with glycuronic acid as urobromalic acid.

There are four ways in which it is possible for avertin to be excreted: (1) as sodium bromide; (2) as unchanged avertin; (3) as urobromalic acid; (4) as an organic compound of bromine other than (2) or (3).

Avertin is not excreted as sodium bromide. The precipitate obtained by adding silver nitrate to the acidified urine of an avertinized rabbit contains only a trace of bromine, while the filtrate contains 95 per cent. As silver nitrate precipitates inorganic bromide, the conclusion is that avertin is not excreted in this form. This is confirmed by the fact that administration of sodium chloride to an avertinized animal does not alter the duration of anaesthesia or the rate of bromine excretion.

Avertin is not excreted unchanged. It forms a precipitate with silver nitrate, and, as stated in the previous paragraph, no such precipitate can be obtained with the urine of avertinized animals. Further, avertin is freely soluble in ether, chloroform, and petroleum ether, and extraction of suitable urines with these solvents gives negative results.

Glycuronic acid is found in the urine of both man and animals after the administration of avertin, and this suggests that the drug may be excreted as urobromalic acid. I have been unable to find any reference to this substance, but its chlorine homologue, urochloralic acid, is said[6] to be soluble in ether and chloroform and to be precipitated by basic lead acetate. No bromine-containing compound can be extracted from the urine of avertinized animals by these solvents, neither can such a compound be precipitated by basic lead acetate.

Avertin can be distilled in steam, but when this process is applied to a suitable urine there is no bromine in the distillate, and we must conclude that avertin is absent from the urine. In addition, the distillate contains no bromine if the urine is first treated with concentrated sulphuric acid in order to decompose any hypothetical urobromalic acid that may be present into glycuronic acid and avertin; this affords strong evidence that the drug is excreted in some other form. In view of the presence of glycuronic acid, it is probable that this is a complex organic compound of bromine.

Summary.

1. Great care must be exercised in the preparation of solutions of avertin for anaesthesia. Decomposition products formed by the action of heat (over 50° C.), light, and air are irritant to the rectal mucosa.

2. In anaesthetic doses avertin has no appreciable effect upon the cardio-vascular system. In larger doses it slows the rate and weakens the force of the heart beat. The coronary vessels dilate and the blood pressure falls.

3. Avertin anaesthesia is accompanied by marked slowing of respiration. Toxic doses cause death by respiratory paralysis.

4. In both man and animals avertin is excreted in the urine over a period of several days. Considerably more than 50 per cent. is excreted in the first twenty-four hours.

5. The form in which avertin is excreted could not be determined. The indications are that elimination occurs in the form of an organic compound of bromine other than tribromethylalcohol or urobromalic acid.

I have to thank both Professor W. E. Dixon and Dr. J. C. Hoyle for their kind advice and criticism.

AVERTIN NARCOSIS.*

BY

GEORGE EDWARDS, M.R.C.S., L.R.C.P.,

ANAESTHETIST, PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM, THE SAMARITAN FREE HOSPITAL, AND THE ITALIAN HOSPITAL, LONDON.

AVERTIN has been used in this country for the last year and a half and has been on the market for the last six months. During the last year I have been privileged to work with Dr. J. Blomfield and Dr. Z. Mennell, and was able to gain some knowledge of its use.

Avertin is tribromethylalcohol, a white crystalline solid. It is soluble in water to the extent of 3½ per cent. at body temperature. When heated above 40° Centigrade or exposed to light for long it decomposes into dibromacetaldehyde and hydrobromic acid. The former substance is extremely irritating to the bowel; the hydrobromic acid is readily observed by its reaction with Congo red reagent and provides a ready and necessary means for testing the purity of avertin solutions.

Introduced into the rectum avertin is readily absorbed from its solution. It is excreted almost entirely by the liver and kidneys, and appears in the urine in combination with glycuronic acid. Straub[1] has recovered from the urine as much as 81 per cent. of the dose given.

The anaesthetic properties of avertin are best indicated by the fact that the chemical manufacturers now call it "the basal narcotic." Full surgical anaesthesia can be obtained, and is occasionally obtained by avertin alone, but the variation in depth of anaesthesia produced by similar doses on different patients is so great that one cannot set out definitely to produce anaesthesia solely by this method. Once a patient is narcotized with avertin, only a very small quantity of inhalation anaesthetic is required to complete the anaesthesia. From the anaesthetist's point of view this is the chief merit of the drug. The patient has much more cause to welcome it. The anaesthetic is given in the ward without fuss, the falling asleep is gradual and peaceful, and the awakening equally so. Even though the narcosis has been very light, there will be no memory of anything from the time of the injection. Further, the events of the next twenty-four or thirty-six hours will not be remembered with any clearness, and the whole horrible business of being anaesthetized and of recovering is thus not only diminished in fact, but is minimized in retrospect. The merits of avertin narcosis are, in short, those of rectal anaesthesia combined with those of deep preliminary and subsequent narcosis.

Avertin is found to be of particular value in dealing with highly nervous patients, with cases of Graves's disease, and, I am told, with children. In patients with respiratory affections it largely reduces the amount of inhalation anaesthetic required, or may enable the operations necessary to be carried out under local anaesthesia. Flessa[2] at the Munich Gynaecological Clinic has used light avertin narcosis in demonstrating patients to his classes. He finds that the patients are not sensible of their exposure, and that the true pain reflexes persist whilst the functional element is obliterated, so that a much more accurate diagnosis is possible. For obstetric purposes, avertin was at first said to be unsuitable, owing to its paralysing action upon plain muscle. However, reports vary exceedingly.

The conditions in which avertin is contraindicated are such as one would expect from its method of absorption and excretion. All inflammatory and ulcerated conditions of the rectum and colon rule it out. Cases with severe renal and hepatic lesions should not be given avertin, although nephrectomy has been performed and cases with severe jaundice have been operated upon under it. Acidosis, advanced cachexia, and serious blood diseases are also given as contraindications. Recent work in Germany by Fribram[3] shows that patients with hyperthyroidism can take massive doses of avertin and can eliminate them quickly. This suggests that patients with deficient thyroid secretion will not eliminate the drug, and that one line of treatment in case of delayed return to consciousness would be the injection of thyroxin. Further, in cases where there is doubt as to the advisability of giving avertin, a determination of the basal metabolism may help in coming to a reasoned decision.

The physiological changes in avertin narcosis are a falling of the blood pressure and a decrease in the respiratory movements. No definite changes in the pulse rate have been observed. The fall in the blood pressure is usually within the limits of that observed in deep sleep, between 10 and 30 mm. I have never seen more than this change, and there appear to be no reports of a greater fall which could have been due to the avertin alone. The respiratory centre is affected and a slight cyanosis is usually observed, more particularly in patients who have had preliminary doses of morphine. The breathing is shallow and the rate normal or slightly quickened. Patients vary a great deal in the amount of cyanosis they show; much depends, of course, upon the general condition of the patient, upon the anatomy of the air passages, and upon the dose of avertin they have had. Marked cyanosis will not occur if the dose has not been greater than 0.1 gram per kilo of body weight, and as long as the airway is kept clear.

The anaesthesia comes on gradually and takes from twenty to thirty minutes to reach completion. The ocular reflexes disappear in the usual way, and with the routine dosage the patients end up with contracted pupils which react to light, with an absent conjunctival reflex, and with no, or only a slight, corneal reflex. There may still, however, be a skin reflex, and pinching the inner side of the thigh or scratching with a needle may cause a movement. A sudden blast of strong ether vapour may produce a cough; this is a useful preliminary test to give one an idea of how much inhalation anaesthetic will be needed. With increasing experience of a routine dosage it is possible fairly accurately to judge what state of anaesthesia has been effected, and to estimate how much pushing of the inhalation anaesthetic will be necessary.

The actual administration of avertin is now a simple proceeding. In the first cases, the weighing out of the requisite amount of powder, the slow dissolving of it in water at 38° C., the testing of the solution, the giving of two rectal washouts before the administration and one after the operation, together with the peculiar anxiety regarding the patient, made an avertin anaesthesia a formidable business. Finding that more often than not a complete anaesthesia did not result, the anaesthetist felt that a great deal of trouble had been taken for no reasonable return. The introduction of a standard concentrated avertin solution ready for dilution has simplified matters, and experience has shown that much lavage of the rectum is not only unnecessary but undesirable, as an excess of fluid in the bowel may interfere with absorption.

The preliminary measures are an enema the night before operation, repeated next morning if it should seem necessary. In emergencies, satisfactory results have been obtained without any preparation of the bowel.[4] Some observers think it good to give a sedative overnight. The desirability of an injection of morphine or of omnopon before the rectal injection appears to be a moot point. Acting upon Dr. Mennell's suggestion, I tried a series of cases with and without omnopon. The difference in the degree of anaesthesia was definite, but the general condition of the patients without morphine was better: respirations were less shallow and there was less cyanosis. As it had been agreed by this time that full anaesthesia was not to be attempted with avertin alone, the omission of the morphine merely slightly added to the amount of ether or chloroform required.

The dosage of avertin is still a matter for discussion; but the general agreement has been that where there is no marked weakness or general infection, 0.1 gram per kilo of body weight is a perfectly safe dose, and this is the dose which is largely used; 0.125 and 0.15 gram per kilo have been used with success, but where there has been trouble it has nearly always been with these high doses. In Germany larger doses still have been tried.[5] I have not been able to get the full results, but am told that cases of Graves's disease stand these doses particularly well.

* A paper read in the Section of Anaesthetics at the Annual Meeting of the British Medical Association, Manchester, 1929.

Avertin is provided in a concentrated solution with amylene hydrate—1 gram in 1 c.cm. The dose works out at between 6 and 8 grams. The appropriate amount of the solution is measured out and enough distilled water to make a 2½ or 3 per cent. solution is heated to 38° C. The avertin is then added and the mixture is shaken till a clear solution results. The most important points are that the temperature must never exceed 40° C. and that the final solution must be free from hydrobromic acid and therefore free from dibromacetaldehyde; 5 c.cm. of the dilute solution are taken and a drop of 1 in 1,000 Congo red solution is added. The colour should remain bright orange red. The blue reaction of free acid is sometimes delayed and it is essential to make the test immediately before administration.

The solution being now ready and satisfactory, it is injected into the rectum fairly slowly through a catheter and funnel. The catheter must be passed well into the rectum proper. The patient is best arranged lying on the left side with a pillow under the pelvis. The 250 or 350 c.cm of solution are easily retained if the injection takes three or four minutes. Attempts have been made to give fractional doses, running in more solution if the anaesthesia produced by the original dose was inadequate. It has been shown that the avertin in solution is more readily absorbed than the water. This makes all calculations with regard to strength of solution useless, and it is impossible to gauge rate of absorption or to prophesy the depth of anaesthesia which will be obtained. If undue depth should be observed at an early stage, washing out the rectum for the purpose of removing any of the avertin that may remain there is a sound proceeding.

In practice, it seems best to give the rectal injection thirty minutes before the advertised time of the operation. This means that the patient need not be disturbed for twenty minutes, and then may be taken straight to the theatre. During the induction period we have endeavoured to keep the patient quiet, to keep the room dark, and to keep out all sources of irritation. Flessa, however, says that some patients resent strongly the sepulchral atmosphere, and that light and noise have no effect upon the induction, so that it is better to allow the ordinary noise and disturbances to go on normally.[6]

Having taken the patient to the theatre, the anaesthetist tests the skin reflexes, and either starts the inhalation anaesthetic at once or, if a fairly deep state has been achieved, withholds the ether till necessary. Ether, C.E. mixture, chloroform, gas and oxygen, or local anaesthetic may be used. If gas and oxygen be used, one has to wait for a severe stimulus to be given by the surgeon before the patient will breathe sufficiently deeply to take in enough of the gases. The amount of ether and chloroform used will be measured in drachms rather than in ounces. Once a sufficient relaxation has been obtained, it is often unnecessary to give any more of the inhalant. The peritoneum that has been relaxed enough for the abdomen to be opened will remain so for closing, unless the operation lasts so long that the avertin effect is wearing off. The usual duration of the narcosis is from one and a half to two hours from the time of the injection. About four hours from the start the patient is usually quite conscious of his surroundings.

The chief care in the nursing is watching the relaxed jaw and tongue; this applies during the period of induction as well as of recovery. A rectal washout used to be given on return to the ward. This is now considered to be unnecessary. Should the patient's condition demand it the routine saline treatment is carried out.

In only one case have I seen any trouble directly due to an avertin anaesthesia. In this case, which was reported in the *Lancet*[7] by Sir Francis Shipway and Dr. Blomfield, the patient died twenty hours after the administration of a dose at the rate of 0.125 gram per kilo. It would seem probable that in that case a deficiency of thyroid secretion had diminished the patient's power of detoxicating and eliminating the drug.

The lines of treatment in cases of prolonged delay in return to consciousness are respiratory stimulation by injections of lobeline, the giving of carbon dioxide and oxygen mixture, and injections of ephedrine to maintain the circulation. So far as I can discover, thyroxin has not been tried; but this would seem a rational method of assisting elimination.

In conclusion, avertin can be used to provide a deep narcosis, which is easily convertible into an anaesthesia by the giving of very small quantities of the ordinary anaesthetics. It is reasonably safe in doses up to 0.1 gram per kilo of body weight. It eliminates nearly all the mental stress which accompanies the usual administration of an anaesthetic. It has no effect upon the respiratory tract. It is well taken by persons with excessive thyroid secretion. It is fairly easy to give.

On the other hand, it is not controllable and cannot safely be used as the sole anaesthetic agent. It has to be prepared with care. It should not be used where there is any disease of the kidneys, liver, or colon, or where there is thyroid deficiency. It is not, as was at first hoped, an anaesthetic that anybody can give at any time. It requires an experienced anaesthetist to control the superimposed anaesthesia. The necessity of giving the injection half an hour beforehand adds to the anaesthetist's duties and makes its use difficult in hospital practice where cases follow each other with rapidity.

In certain cases and types of patients avertin is a great help. As a routine anaesthetic agent, it is hardly practicable.

THE TREATMENT OF TORTICOLLIS.*

BY

B. WHITCHURCH HOWELL, F.R.C.S.Eng.,

SURGEON TO THE QUEEN'S HOSPITAL FOR CHILDREN, LONDON; SURGEON TO THE BROOKFIELD ORTHOPAEDIC HOSPITAL; ORTHOPAEDIC SURGEON TO THE ESSEX COUNTY COUNCIL.

Torticollis or wry-neck is a very rare deformity, occurring once in every 150,000 births. Congenital club-foot is ten times as frequent. The outstanding deformity is the tilting of the head towards the affected side, with rotation of the chin forward and away from the affected side. Secondary deformities are facial asymmetry and scoliosis, chiefly of the cervical region.

The cause of the deformity is contraction of the sterno-mastoid muscle, more particularly its sternal head. Its origin is either congenital or acquired, the following being the chief varieties:

A. *Congenital.*—(1) Prenatal; (2) natal.
B. *Acquired.*—(1) Rheumatic; (2) reflex—for example, tubercle of cervical spine; (3) ocular; (4) *spasmodic*, etc.

The congenital variety, as indicated above, has two subdivisions—prenatal and natal—and there are several theories as to their origin.

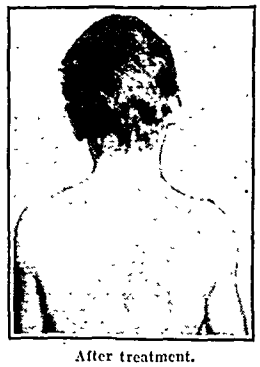
1. *Prenatal.*—The prenatal subdivision includes those due to abnormal posture *in utero*, giving rise, on the one hand, to temporary or permanent shortening of the sterno-mastoid, or, on the other, to localized fibrosis and contracture of the muscle from interference with the blood supply—thus being allied to Volkmann's ischaemic paralysis. The rarer forms are due to abnormal development of the cervical vertebrae, which may be unusual in number and often wedged. A certain percentage of the latter are associated with Sprengel's shoulder or congenital elevation of the shoulder. In addition, cervical ribs may be present. The contracture of the sterno-mastoid is usually on the right side, and is very rarely bilateral. I have personal records of three cases of bilateral torticollis, each one of which was associated with congenital abnormalities of the cervical spine, whilst in one Sprengel's deformity was present.

2. *Natal.*—The natal subdivision of the congenital variety is generally associated with a difficult confinement. The presentation is usually a breech, when there may

* A paper read in the Section of Orthopaedics at the Annual Meeting of the British Medical Association at Manchester on July 25th. This was illustrated by photographs of patients before, during, and after treatment. Photographs of the operation table used are reproduced at page 721.

be trauma of the after-coming head and neck, resulting in rupture of fibres of the sterno-mastoid, with or without the formation of a haematoma within its sheath. Bruising of the neck is not always present, however, and in these instances the so-called haematoma is found generally in the middle and lower third of the substance of the muscle. From such examples arose the theory of the congenital origin of the deformity—that it is due to intramuscular fibrosis during intrauterine life. This theory is borne out by anatomical experiments which show that the blood supply of the lower half of the muscle is more easily interfered with by torsion of the neck *in utero*, thereby causing ischaemia of that part. On the other hand, I have had instances of torticollis associated with Erb's paralysis on the same side, thus supporting the traumatic theory of the cause of the deformity. In one instance there was a history of heredity, the mother of the patient also suffering from torticollis. With regard to sex incidence, females were definitely in the majority.

Before treatment.



After treatment.

In this paper I do not propose to discuss the acquired varieties of torticollis, the differential diagnosis of which can be made by a careful clinical examination of the patient, in particular of the eyes, the spine, and the x-ray films, after which the appropriate line of treatment can be carried out.

TREATMENT OF CONGENITAL TORTICOLLIS.

This depends upon the age at which the patient is brought to the orthopaedic surgeon. The earlier the better, as a complete cure within a few months can then be promised.

Early Cases.

If the child be brought within a few days of birth then the cure is simple, non-operative, and should be complete within three months. To secure this the orthopaedic masseuse rotates and tilts the head to the position directly the reverse of the deformity, whilst the mother pulls down the shoulder and arm on the side of the deformity. After these movements have been repeated a number of times the masseuse kneads the contracted muscle, especially in the neighbourhood of the so-called haematoma should this exist. The treatment is repeated daily, and in the intervals the mother endeavours to copy the masseuse. Correct posture of the child whilst being carried can also help in the cure. Just as a mother can cause scoliosis in her infant by carrying it constantly on the same hip, so can she, by reversing the process, cure that deformity. Exactly the same simple method can be applied by the mother to the cure of torticollis.

Late Cases.

These have marked shortening of the sterno-mastoid, with or without facial asymmetry and scoliosis. In all such patients operation, followed by suitable exercises and re-education, is the only cure. I have operated upon 24 cases, of which 23 were of the true congenital variety. The only acquired type was a case of spasmodic torticollis in a woman, in whom the condition had existed for a considerable number of years. The operation in this particular case consisted in crushing, and thereby paralysing for some months, the muscular branches of the spinal accessory nerve which supply the sterno-mastoid, with complete relief for a considerable time.

Of the 23 cases of true congenital torticollis all except 3 were operated upon by the subcutaneous method, the sternal end of the muscle being divided with a blunt Jones tenotome. Of the 3 cases treated by the open division of the sterno-mastoid, 2 were tackled at the lower end, and one at the upper end below the mastoid process. This latter case occurred in a girl, and was the only case in which an incomplete cure resulted from the subcutaneous division of the sternal end. Open division of the upper end resulted in a complete cure, the operation scar being hidden by the hair.

Details of the Subcutaneous Operation.

The essentials of the operation are extensive preparation of the skin, including both upper limbs; adequate towelling off of the operation area; very skilled assistance, consisting of chief assistant, together with helpers to hold and pull upon the upper limbs; endotracheal anaesthesia whenever possible; adequate airway; maintenance of over-correction of the deformity after tenotomy by a plaster-of-Paris cast, followed by exercise and re-education by an orthopaedic masseuse after its removal some weeks after the operation.

Before treatment.

During treatment.

After treatment.

The patient having been anaesthetized, a flat sandbag is placed transversely beneath the shoulders, the head held well over the end of the table, the skin prepared, and the towels applied. Each upper limb is held adducted by the hand by assistants, whilst the chief assistant takes sole charge of the head, and moves it as required by the surgeon during the operation. He is seated on a stool, with the table so arranged that he can hyperextend the head. The head is flexed to relax the sternal end of the muscle, and the skin is picked up with toothed dissecting forceps, held in the left hand, about an inch above the clavicle close to the sternal end. This facilitates the

introduction of the tenotome beneath the skin. The forceps being dispensed with, the finger and thumb of the left hand firmly grip the sternal portion of the muscle and lift it away from the deep structures of the neck. The tenotome is then slid transversely behind the tendon from the inner side, and a moderate degree of tension put upon it by traction on the head by the chief assistant, a similar amount of traction being applied at the same time to the upper limb on the affected side. The tendon is thus cut through slowly and the tenotome withdrawn. The surgeon then kneads the muscle, especially the clavicular portion, whilst the chief assistant stretches the contracted tissues by rotation and extension of the head. A dressing is now applied, followed by a plaster-of-Paris jacket, with the head in the over-corrected position, and the shoulder on the affected side pulled well down. The application of the plaster cast is much facilitated if the operation be performed on the orthopaedic operation table described at page 721 of this issue, which was invented some years ago, and shown at the Orthopaedic Section of the Royal Society of Medicine on February 7th, 1928. If this be not available, then the plaster should be applied with the patient lying on a simple pelvic rest. The points to be emphasized in its application are pressure beneath the chin, mastoid process, and shoulder on the affected side, and adequate airway.

The plaster jacket is not as irksome as might appear, patients being able to walk, and even play football and ride a donkey. This is bi-valved in four weeks' time, and exercises and re-education are commenced by the masseuse. At first the exercises should be carried out in the prone position, with the head low to avoid the faintness sometimes experienced on removal of the jacket. It is worn as a corrective splint for another four weeks, and then it is discarded. A complete cure usually results in three to six months, depending on the degree of deformity present *per se*, as well as the secondary ones; naturally the facial asymmetry takes longest to disappear.

It should be emphasized that the masseuse undertaking the treatment should make the acquaintance of the patient some days before the operation in order to initiate the corrective exercises which will be necessary afterwards, and should, of course, be present at the operation.

Results of Operation.

The results of operation by this method were complete cures in 19 out of 20 cases; the one case which was a partial success was made a complete one by open division of the attachment at the mastoid process.

The risks of the closed operation are not great provided the tendon is carefully lifted from the deeper structures of the neck and the surgeon has adequate skilled assistance. All the instruments necessary for the open division of the tendon are, of course, readily sterilized for use should anything unforeseen arise. The resulting fine pinprick scar is of great cosmetic importance to a girl.

Indications for Open Operation.

The indications for open operation are: (1) incomplete cure or relapse from the subcutaneous method; (2) cases in which there are other abnormalities—for example, Sprengel's shoulder, or congenital cervical scoliosis, as shown by the presence of wedged vertebrae, etc. In such cases the deeper structures are contracted, and will require stretching or even division.

The incision is preferably obliquely transverse over the sternal end of the clavicle to make the scar as inconspicuous as possible, the platysma is divided, and then the sternal head of the muscle over an elevator. The clavicular head seldom gives trouble, except in those instances where a previous operation may have caused fibrous tissue formation. The head is then stretched to the over-corrected position, the soft tissues carefully sewn up with fine catgut, and the skin with fine salmon gut, and a plaster jacket applied. The resulting scar is disfiguring, and tends to broaden as years go by.

Contraindications for Operation.

1. Those cases in which *x*-ray films show a marked congenital bony deformity, generally due to wedged vertebrae, with perhaps cervical ribs.

2. Bilateral torticollis. I have seen three such cases.

3. Those cases in which the torticollis is secondary to disease of the spine—for example, tubercle.

In all the above, where bony deformity is present, it would be of little value to divide the contracted soft structures, as the bony ones would remain, and these are not correctable.

Summary.

This paper has been written, and these photographs of cases before, during, and after treatment have been shown, in order to emphasize that torticollis may be prevented by careful ante-natal examination of the mother to secure the simplest presentation, avoiding natal injury. Further, the younger the infant the sooner the cure. Lastly, the subcutaneous tenotomy of the sterno-mastoid muscle gives a complete, lasting, scarless result.

CONGENITAL POLYCYSTIC DISEASE OF THE KIDNEYS AND LIVER.

BY

GRAHAM C. CAMPBELL, M.R.C.S., L.R.C.P.,

LATE RESIDENT MEDICAL OFFICER, ROYAL UNITED HOSPITAL, BATH.

The following case of congenital polycystic disease of the kidneys and liver is interesting not only on account of the pathological condition of the liver, but also because of the family history. As happens in so many similar cases, the condition of the kidneys and liver was only discovered at post-mortem examination; during the lifetime of the patient it had never been considered in the differential diagnosis of his illness.

History.

A. H., a male aged 55, saw his family doctor in February, 1929. He had been sent by his wife because of occasional vomiting, from which he had suffered during the preceding fortnight. His own mental outlook was curious, in that he seemed quite unconscious of the fact that he was ill. At that time he was very anaemic; his tongue was pale and flabby, but there was no glossitis; his liver was slightly palpable in the right hypochondrium. The illness was diagnosed as Addison's anaemia, and he was ordered to rest, and was treated by means of liver, arsenic, and hydrochloric acid. Following the adoption of this treatment, especially after taking the liver, he vomited several times, and the administration of liver was therefore stopped. Two days later he had a copious bright red haemorrhage from the rectum; rectal examination revealed no abnormality. He was given kalzana tablets and an intramuscular injection of 4 c[illegible] but this and subsequent injections of the [illegible] Following the second injection he had [illegible] right nostril, which was successfully plugged with gauze soaked in adrenaline. The next day bleeding occurred from a small denuded area in the situation of the lower left canine tooth; this was finally arrested by a turpentine application. A blood count made at this time showed marked diminution in the number of red cells (2,500,000 per c.mm.), but no obvious change in the white count. The urine was pale in colour; its specific gravity was 1010; it contained no sugar, but traces of albumin and an occasional cast were found. The optic discs though pale were normal, and no retinal haemorrhages were seen.

The patient now began to be rather sleepless, and there was marked tremor of the fingers. The bleeding from the rectum persisted, and to check it he was given by mouth an emulsion of half an ounce of turpentine with half an ounce of castor oil. Following this treatment haemorrhage stopped for one day, but it reappeared on the next day. Neither suppression of urine nor haematuria followed the administration of turpentine.

He was admitted to hospital on February 16th, about a fortnight after his first visit to his private doctor. He complained of a dull ache in the right loin, and preferred to lie on his left side. In hospital he was given an intravenous injection of calcium chloride, without, however, any apparent effect on the haemorrhage. He died on February 18th.

Post-mortem Findings.

Kidneys.—Both kidneys were equally enlarged and cystic; each weighed 2 lb. and measured 6½ inches from its upper to lower pole and 3¾ inches in breadth. The cysts varied in size from that of a pea to that of a walnut.

Liver.—The liver was uniformly enlarged, and weighed 3½ lb. Its anterior surface measured 6¾ inches by 6¾ inches by 7½ inches. Its whole substance was thickly studded with small cysts, the size of which varied up to that of a hazel nut.

Other Organs.—No cysts were seen in the pancreas, and no pathological condition was found in any other organ.

Microscopical Examination.

The section of liver examined microscopically showed typical congenital cysts. Normal liver tissue was seen, between which were spaces lined with a flattened epithelium. The normal tissue was not compressed, and the cysts probably arose from ordinary liver-forming cells very early in their development.

Family History.

The patient was the youngest of ten children, one of whom died at birth; of the rest, only one is alive, a woman aged 69, apparently in good health. His mother died from Bright's disease, aged 56; his father (the cause of whose death is unknown) when 85. The following is a list of the children in order: (1) a male, died at the age of 1 year from convulsions; (2) a female, aged 69, still alive; (3) a female, died from convulsions, aged 2; (4) a female, died at the age of 49, and post-mortem examination revealed cystic kidneys; (5) a female, died of kidney trouble, aged 45; (6) a male, died from convulsions, aged 2; (7) a female, died of cancer (organ not specified), aged 55; (8) a female, died from convulsions, aged 1; (9) the patient himself. From this list it will be seen that of his brothers and sisters two are known to have had cystic kidneys, one died of kidney trouble, one of cancer, and four died under the age of 2 from convulsions. It is possible that the latter four may have suffered from uraemia.

Discussion.

Teuscher[1] has suggested that cystic formation in the kidneys and the liver depends on an anomaly in the germ plasm. In examining the liver she always found openings between the cysts and the bile passages, and concluded, therefore, that cyst formation was due not to failure of bile ducts to establish their connexion with the larger bile passages, but to a capacity for growth on the part of the epithelium. She suggested that the cystic development was an expression of a perverted tendency, widespread in the body, for tissues of the excretory ducts to multiply at the expense of the more highly differentiated glandular tissue. The above family history appears to confirm her theory that a predisposition to the disease is hereditary, since two of its members were known to have suffered from cystic disease, and five others may have done so.

I am indebted to Dr. Rupert Waterhouse for permission to publish this case.

MEDICAL, SURGICAL, OBSTETRICAL.

SIMPLE MASTOIDITIS WITH SYMPTOMS OF CEREBRAL ABSCESS.

THE following case, which recently came under my care, is of interest because at the time of operation I was quite prepared to find a temporo-sphenoidal abscess, the symptoms and general appearance of the patient pointing to this condition.

A married woman, aged 58, first consulted me about six months ago; she was suffering from acute suppurative otitis media of the left ear. On examination the membrana tympani was found to be very red and inflamed, and a small perforation was present in the postero-superior quadrant, through which thick pus was oozing. There was a certain amount of mastoid tenderness, and general malaise with a slight rise of temperature. Under treatment the condition improved, the tenderness disappeared, and the discharge, which was profuse at first, later became less.

After the eighth week an exacerbation occurred, and, the perforation already present being inadequate, a fresh incision was made in the drum, thereby increasing the size of the existing opening. This only partly relieved the pain and tenderness, and a second operation was performed twelve days later to allow free exit to the discharge, which was very thick and plentiful.

The general condition *became worse, and when I* saw her fourteen days later she presented the following picture. She looked extremely ill and wasted, with a rather terrified expression. She complained of deep-seated pain in the left temporal fossa, and tenderness over the squamo-parietal bone. Sleep had been impossible for several days owing to the intense pain; sickness and retching were complained of. The temperature was subnormal, being 97.6° F., and the pulse was 70; the aural discharge had ceased. There was no oedema or tenderness on pressure over the mastoid region, but slight pain was experienced on deep pressure beneath the tip of the mastoid and upper part of the jugular vein.

The symptoms were those of a temporo-sphenoidal abscess, and, as the patient was obviously very ill indeed, could not endure the pain much longer, and was becoming unbalanced mentally, I decided to operate without delay. I made the usual post-aural incision, and exposed the entire mastoid region; the bone looked healthy but sclerosed. On chiselling down to the depth of a quarter of an inch I struck a large quantity of pus coming from the middle ear and antrum, and also from the deep surface of the mastoid tip. Having cleared out the cells, which were numerous and extended well up on the squamous plate of the temporal bone and into the zygoma, I found the tegmen quite healthy. Not being satisfied, I removed it, and exposed the dura of the middle fossa, which was also healthy. On these findings, and as the symptoms present did not justify me in doing so, I decided not to open the dura mater. The deep surface of the mastoid process was entirely eaten away, and the lower end of the lateral sinus exposed and covered with granulations. Just towards the end of the operation I must have slightly damaged the sinus, as profuse haemorrhage occurred, which could only be stopped by plugging the lower part of the cavity. This was left *in situ*, and having plugged the rest of the operation cavity with gauze soaked in iodoform emulsion, the skin incision was closed with the exception of the lower end, which was kept open for drainage and lavage. The patient made an uninterrupted recovery.

This case is interesting because it shows: (1) the presence of extensive mastoid disease with what one might almost call an absence of symptoms of mastoiditis; (2) the presence of symptoms of cerebral abscess in the absence of any intracranial complication.

HERBERT V. O'SHEA, M.D., M.Ch., D.L.O.

INGUINAL HERNIA IN A MONORCHID.

IN view of the interesting questions raised by the occurrence of a right-sided oblique inguinal hernia in the absence of a descended right testicle, the following clinical details of such a case seem to be worth recording.

A Hindu male labourer, aged 31, was admitted into the Ranbir Hospital, Jind, May 22nd, with a reducible swelling in the upper part of the right side of the scrotum of over ten years' duration. The swelling had been small at first, but it eventually reached the size of a big plum, descending very frequently and on the slightest exertion; when down it was not easily reducible, and the patient could no longer undertake any hard work. He attributed the condition to an attack of influenza in the pandemic of 1918. On examination of the upper part of the right side of the scrotum in which there was no testicle a soft swelling as large as a big plum was found; there was pulsation on coughing but no testicular sensation. It could be reduced and the opening behind it could admit two finger tips. On deep palpation in the region of the internal abdominal ring, no swelling could be made out. There was no history of there having been a right testicle in the scrotum nor of any operation on that side; no scar was found; the left testicle was apparently normal. The patient had married about twelve years previously and was the father of five children, of whom four had died, the survivor being 8 years old. Virility was said to be unimpaired, and no other member of the family is monorchid. The patient was of a sturdy appearance and had a strong abdominal wall.

On May 23rd the usual incision for inguinal hernia was made; the aponeurosis of the external oblique was incised in the direction of its fibres and the sac was identified underneath it; it was separated but no cord could be made out. A small opening was made in its dependent part, and the great omentum was seen. The sac was easily replaced into the peritoneal cavity, traced towards the inner side, and found to be firmly adherent to the pubic spine. Efforts were made to separate it from its attachment, but this was found difficult, so it was cut across as near the bone as possible; the neck was tied, and the distal portion removed, the stump being transfixed in the usual way. The inferior epigastric artery was seen pulsating on the inner side of the sac. It was noted that *the conjoined tendon and the aponeurosis of* the external oblique were not quite uniformly thick, otherwise they were strong and the abdominal wall was quite firm. The wound was closed in the usual way; the patient made an uneventful recovery and was discharged cured on June 11th. One month later, and again after two months, he remained perfectly well and was anxious to resume his occupation; he had started carrying some heavy loads, though advised to abstain from such work for six months.

An interesting point is that the case is one of right-sided oblique inguinal hernia in a monorchid. It appears that the gubernaculum developed normally and followed the usual direction, as did the peritoneal sac, so it was not clear why the testicle lagged behind. Was this due to the absence of some substance in the gubernaculum which failed to attract the testicle down, or was the testicle totally absent on that side? A second question is why it took so long for the peritoneal contents to make their way into the sac; perhaps it had become sealed, though imperfectly, and, later, when the patient was debilitated by influenza in 1918, the great omentum succeeded in working its way through the internal abdominal ring. Thirdly, if the sac was attached to the pubic spine, how did the swelling appear in the upper part of the scrotum? It appears that the contents of the sac while making their way towards the fundus encountered the resistance of the bone, and took the path of least resistance—the external abdominal ring—making a loop in the lower part of the sac. This case evidently supports [illegible] theory for inguinal hernia suggested b[illegible] ave should be glad to know whether [illegible] been recorded.

A TWIN BREECH CONFINEMENT.

If the proportion of twin pregnancies is 1 in 90 births, and the proportion of breech presentations that come to full term is 1 in 60, the occurrence of full-term twins, both of which present by the breech, must be very rare indeed. The following clinical details of such a case would seem, therefore, to be worthy of record.

A woman suffered from irregular periods for which I advised curetting, but she became pregnant before this was performed. The pregnancy was associated with the presence of a considerable amount of amniotic fluid, a quantity of which escaped on two occasions during the fifth and the sixth months without interfering with the gestation. The limbs were readily felt through the abdominal wall. There was much water present up to the time of labour; a few days before this was due I felt a leg presenting, and recommended her removal to a nursing home or a consultation. As the patient preferred to remain at home, Dr. M. G. Pearson saw the case with me. On his examination the leg could no longer be felt, but he diagnosed a twin pregnancy; a head was palpable about the level of the umbilicus, and the child was clearly in the posterior position.

At the onset of labour a few days later a good-sized bag of waters presented, but the foetal head could not be felt. When the os was fully dilated, I ruptured the membranes under an anaesthetic, and, after some delay, assisted the delivery of a breech by the carefully applied forceps. The rest of the delivery was accomplished without trouble or injury to the child, which was a girl, who readily commenced to breathe when the body was sprinkled with cool water. As the labour pains continued without delivery of the placenta or presentation of the other child, I perforated the amnion which separated the two sacs, and a fair amount of amniotic fluid escaped. It was some time before anything presented, and, in view of the weakness of the pains, I used forceps to assist the passage of the breech of the second child over the brim. The occiput being posterior, I had a little more difficulty in bringing the arms down without injury than I had experienced in the delivery of the first child. The second child was a girl; both were of full size, and both were delivered without any injury to the mother or to themselves. After the delivery of the second child there was an escape of much amniotic fluid, and 0.5 c.cm. pituitrin was injected intramuscularly as a safeguard against post-partum haemorrhage, but no trouble was encountered. Except for a slight rise in temperature on the fifth day, which responded to treatment with a hot douche, quinine, and purgative, the mother was not inconvenienced by her exceptional experience. I had attended her at her two previous confinements, which were normal.

The case was of particular interest to me because the last confinement I attended was a breech presentation of a full-time female child in a persistent posterior position. I had difficulty in the delivery of both arms because the patient started to recover from the anaesthetic when I had delivered the legs; the need for haste in the interests of both mother and child resulted in some crushing of the brachial plexus and the fracture of a humerus, which necessitated the use of a plaster for three weeks.

The principles of treatment advocated in manuals of midwifery are hard to follow when one has to attend a difficult confinement without the assistance of a skilled anaesthetist, and when there are special reasons against leaving the case unfinished once labour has set in.

Durban, South Africa. F. G. Cawston, M.D.Camb.

Reports of Societies.

LATENT SINUSITIS AS A CAUSE OF RETROBULBAR NEURITIS.

In the Section of Ophthalmology of the Royal Society of Medicine, on October 11th, Dr. Rosa Ford, ophthalmic surgeon to the South London Hospital for Women, gave an account of two cases of retrobulbar *neuritis* due to a latent sinusitis which every usual method of diagnosis had failed to detect.

Dr. Ford remarked that at a previous discussion three years ago, held in conjunction with the Laryngological Section, several members expressed the opinion that retrobulbar neuritis was rarely, if ever, the result of sinus disease. The two cases she now demonstrated both belonged originally to the category of cases which were without ascertainable cause, and the first of them had so remained for three and a half years; but there now seemed reason to believe that both were due to a latent sinusitis, the diagnosis of which was extremely obscure.

The first was the case of a man, aged 31, who saw Dr. Ford in 1926 for a blind right eye, with central scotoma and vision 2/60. Sinusitis was suspected, but his only symptom was a quite negligible post-nasal catarrh of three years' duration, and the only sign a few pus cells in the washings from the posterior sinuses, giving a culture of *B. alkaligenes*. These were disregarded as probably contaminations. Under general treatment the vision slowly improved to 4/10. Two years later the man reported that the improvement had been maintained, but that he had remained subject to frequent attacks of misty vision and slight pain at the back of the eyes. These eventually ceased, but his post-nasal catarrh at the same time became marked, until it interfered with his night's rest. Nasal examination showed signs of double ethmoiditis with muco-pus in quantity on the right side. The speaker's interpretation was that the sinusitis was at first latent, and the very inadequate drainage into the nose showed itself by a slight post-nasal catarrh. The pent-up secretion affected the optic nerve, causing the central scotoma, but whenever the secretion found more adequate drainage the vision cleared, and when the drainage was less than usual an attack of misty vision ensued. With the establishment of free drainage, as shown by the marked catarrh, all eye symptoms ceased.

The second case was that of a woman aged 42, with central scotoma in the right eye, temporal contraction of the field, and 6/60 vision. There was no catarrh, but she had severe pain over the right cheek. In view of the blindness and pain it was decided to operate, and the antrum, when opened, was found to contain clear jelly-like mucus and a small polypus, which seemed clear evidence of a low-grade infection. The effect of performing a right partial middle turbinectomy and the opening of the ethmoidal cells was a marked relief of pain, shrinking of the scotoma, and enlargement of the field, which lasted about five weeks and then relapsed, the nose being then reported perfectly normal. The result seemed to point completely to a causative sinusitis, yet all the usual methods of diagnosis left the rhinologist uncertain of its presence.

In these cases clinical examination failed to detect the cause (as had been reported in like cases by other observers); exploration failed, for no macroscopic pus was seen in the washings from either case; culture of the washings from the sinuses also failed, for in the first case the *B. alkaligenes* was not considered to be of pathological significance, and in the second case the culture was sterile; *x*-ray examination failed, being negative in the first case, and indefinite in the second. Sinusitis being so extremely elusive, she thought that two conclusions could be drawn: (1) that it would be very helpful to ophthalmology if rhinology could give some more conclusive test than those in ordinary use, and (2) that retrobulbar neuritis might be more often due to a latent sinusitis than had been thought, and that perhaps one might look in this direction for a solution of some of those unexplained cases which were so disturbingly numerous.

Retrobulbar neuritis showed a strong tendency to spontaneous recovery, as had happened in the first of these cases, but she thought the case showed that there was some danger in waiting for this to occur, for recovery had been extremely slow, and even now, nine months after complete cessation of eye symptoms, there was relative dimming of the whole field. To wait for spontaneous recovery was to run the risk of permanent damage to the optic nerve.

After discussing the respective parts to be played by the rhinologist and the ophthalmologist, pointing out that while these cases were altogether nasal the key to their solution was often altogether ophthalmic, she disputed the view sometimes responsible for a hopeless prognosis in these cases—namely, that a retrobulbar neuritis of obscure origin might be an early sign of disseminated sclerosis. It might not be disseminated sclerosis at all. Moreover, if disseminated sclerosis was a subacute inflammation of the nervous system, possibly of autogenous origin, it was doubly important to eradicate any doubtful focus of infection, such as a latent sinusitis, when the retrobulbar neuritis was acting as a herald of its onset.

Reviews.

THE EYE IN GENERAL MEDICINE.

BOOKS which present opinions and methods of practice based upon a long and carefully gathered personal experience can hardly fail to be of value to those whose professional responsibilities are yet at the beginning; and, indeed, so wide and so varied is the clinical picture that even a senior may welcome a tale well told by a colleague. It is in this order of contributions that Dr. MAITLAND RAMSAY'S *The Eye in General Medicine*[1] must be placed. The book is neither a systematic textbook on diseases of the eye nor an ordered description of the disturbances to be found in the eyeballs in general or constitutional disease. Rather it may be described as the author's thoughts about the eye and its diseases and the application of these thoughts to various practical situations. Through all the chapters runs the claim that in the eye may be studied readily and with advantage many of the pathological processes to which other parts of the body, equally with the eye, are liable; in other words, that a wide mental outlook in the practice of ophthalmology recognizes local changes as parts of a larger whole, and affords guidance in dealing with the symptomatic claims that these changes establish.

Thus the pain caused by spasmodic contraction of the unstriped muscle of the iris has its parallels in angina pectoris, in intermittent claudication, in intestinal colic, and in strangury, for in each of these disturbances unstriped muscle in spasm is concerned; in the pneumococcal ulcer of the cornea may be observed the morbid processes which mark the pulmonary changes produced by the pneumococcus; a hypopyon has its analogue in an empyema; and the vascular derangements which in an eyeball produce tension and glaucoma are comparable to those which in the kidney establish tension and anuria. Stated in the bald fashion here summarized these propositions may seem somewhat extravagant, but as developed and argued in Dr. Ramsay's pages they have an inviting quality, and they certainly challenge attention and thought.

Moreover, this identification of the processes of disease in the eye with the processes of disease elsewhere is not presented as a mere academic exercise. On the contrary, it is urged that the recognition of this truth has educational and practical values. From it follows the thesis that pathological disturbances, as these come to the attention of the clinical ophthalmologist, are not detached and isolated events which require mere local regard and treatment, but that, equally with other symptoms, they set up a demand for a complete inquiry into the patient's history and an investigation of all the clinical facts of the case. The reward, it is urged, is not only the security which comes from knowledge, but also—and this is strongly pressed—an enlarged opportunity for successful treatment. This order of teaching is applied in all sections of the book, and particularly in chapters which deal with ocular symptoms due to disordered carbohydrate metabolism, to defective elimination, and to toxic agents; and a like comprehensive view is exhibited in discussing the medical aspects of eyestrain, the relation of the capillary circulation to glaucoma, and the ocular manifestations of cardio-vascular disease.

Of clinical ophthalmology, in short, Dr. Ramsay takes no narrow view. He is urgent that every practitioner should cultivate the ophthalmoscope as a routine method of examination; similarly he pleads that ocular disturbances and diseases should be viewed in relation to the body as a whole, and that upon this inclusive examination the therapeutic needs of the patient should be met. Though the teaching is decided or even emphatic, it is not arbitrary, and the argument is presented in a pleasing and lucid fashion. In preparing his book as a second edition Dr. Ramsay has given to his readers many things of high value, and we feel sure the event will prove that he has not laboured in vain.

[1] *The Eye in General Medicine.* By A. Maitland Ramsay, M.D., LL.D. Second edition of *Diathesis and Ocular Diseases.* London: Baillière, Tindall and Cox. 1929. (Demy 8vo, pp. x + 255. 12s. 6d. net.)

THE TOXAEMIAS OF PREGNANCY.

MONOGRAPHS on medical subjects may be written from one of two aspects: they may aim at setting forth a particular view of the subject, or at giving a comprehensive review of many varied, and often incompatible, theories. The first method has the advantage that it enables the author to present a more or less logical sequence of ideas, and to give a more readable, if more biased, account of the subject. The second method serves a different purpose, and has been adopted by Dr. STANDER in his book on *The Toxæmias of Pregnancy.*[2] He is to be congratulated on the way he has considered every theory, weighed every piece of evidence, and reviewed so wide a field of literature; it is not owing to any fault in his presentation that he leaves the reader quite bewildered as to the present state of our knowledge of the toxaemias of pregnancy.

Perhaps in no other subject is knowledge so chaotic; in none is it more difficult to compromise the various conflicting theories or to correlate the various disconnected pieces of evidence. It is obvious that mutually exclusive theories cannot all be true, and some must therefore be discarded. Unfortunately no theory is sufficiently established to justify the unbiased observer in rejecting all the rest. A second misfortune hangs round the subject, and that is the overwhelming rate at which "evidence" has collected during the last ten years. During this period biochemistry and biophysics have been the main lines of approach, and although at first they promised great advances, it must be admitted that despite our increased knowledge of the metabolic changes in normal and abnormal pregnancy, we are not really any nearer the solution of the problem of the "toxaemias of pregnancy." The hope that biochemistry would bring us nearer to an understanding of the cause of eclampsia and allied conditions has not been realized. Dr. Stander, who devotes a large part of his book to a review of this aspect of the subject, has succeeded, by discarding the useless work and correlating the rest, in presenting a clear statement of existing knowledge of the metabolic changes associated with the "toxaemias."

Bound up with our ignorance of the nature of these diseases is the difficulty of classifying them, and it is doubtful whether Dr. Stander's classification is more satisfactory than the rest. He rightly points out that, albuminuria being a laboratory finding and nothing more, the term "albuminuria of pregnancy" should not be used to denote any particular type of disease. In its place he suggests the term "low reserve kidney" to denote a condition found in previously healthy women whose pregnancy is associated with an albuminuria which rapidly clears up after delivery. The albuminuria may or may not recur with subsequent pregnancies, but the essential thing is that the kidney lesion does not become progressively worse with each attack. In this respect the patients with "low reserve kidney" differ from those with a true "nephritis," who, according to Dr. Stander, invariably become worse with each pregnancy. In addition to these two groups he recognizes two others—eclampsia and pre-eclampsia. The criterion of eclampsia is the occurrence of fits, while pre-eclampsia is "limited to the relatively small group of cases in which the patient presents the signs, symptoms, and laboratory findings of eclampsia but has not yet developed convulsions." The weakness in this classification seems to be in the confusion of criteria. The "low reserve kidney," and the "nephritis" groups are based essentially on the subsequent history of the patients; the "pre-eclamptic," and the "eclamptic groups," upon the immediate findings. Apart from quantitative differences there seems to be no fundamental distinction between "low reserve kidney" and "pre-eclampsia," and apart from a single symptom—convulsions—no difference between "pre-eclampsia" and "eclampsia." In the present state of our knowledge it would seem simpler to regard all the cases in these three groups as having a common pathology. It is true that the biochemical findings differ in the two groups ("low reserve kidney" and "pre-eclampsia"),

[2] *The Toxæmias of Pregnancy.* By H. J. Stander. Medicine Monographs, Vol. XV. London: Baillière, Tindall and Cox. 1929. (Med. 8vo, pp. xi + 161. 13s. 6d. net.)

but the differences are only of degree, and it is impossible to draw any hard-and-fast line, clinical or chemical, between the two conditions. The classification adopted can possibly be defended on clinical and, to a less extent, on biochemical grounds, but it has not helped to clarify the fundamental problem of the etiology of the kidney changes associated with pregnancy.

The sections on vomiting of pregnancy and acute yellow atrophy are comprehensive, and include detailed accounts of the associated changes in the chemistry of the blood and urine. Taking it as a whole the monograph offers the reader a wide survey of the available knowledge and theories about the toxaemias of pregnancy. The summary of recent work could have found no more able author than Dr. Stander, who has himself contributed so much original biochemical research to the subject.

APPLIED PHARMACOLOGY.

THE third edition of *Applied Pharmacology*,[1] by Professor A. J. CLARK, who speaks with the authority and experience of teaching chairs in the three Universities of Capetown, London, and Edinburgh, fully maintains the high opinion expressed by one so well qualified to judge as Professor W. E. Dixon in these columns (1923, i, p. 514) about the first edition. In spite of its natural increase in size and value the price remains the same; two new chapters have been added—on the pharmacology of the skin and on inorganic metabolism, and those on the vitamins and the pharmacology of the liver have been rewritten in the light of more recent knowledge. In the chapter dealing with the skin, in which the help of his colleague Dr. G. H. Percival is acknowledged, the use of thallium acetate as a depilatory (the nature of its action being unknown) is described, and reference is made to the toxic effects which should not occur if the dose is carefully calculated and the drug only administered to children under puberty. The summary of inorganic metabolism contains sections on poisoning due to excessive ingestion of water, and Professor Clark points out that, although it is difficult to induce this intoxication in healthy persons unless pituitrin is given at the same time, mild degrees of it may easily be produced in nephritis. The important subject of calcium metabolism, which, like those of acidosis and alkalosis, is mentioned elsewhere in special connexions, is clearly epitomized. Under the heading of pharmacology of the liver the treatment of pernicious anaemia by liver is described as resembling the insulin treatment of diabetes in that it relieves rather than cures the condition. Well written and full of information, this handbook is assured of many more editions.

CLINICAL METHODS.

GOOD books on the various methods of physical examination employed at the bedside already exist, but a warm welcome must be extended to a new arrival in Dr. S. A. LOEWENBERG'S *Diagnostic Methods and Interpretations in Internal Medicine*.[2] This is a good book because throughout the fundamental object of all diagnostic measures is kept in mind—namely, to enable the person conducting the physical examination to visualize, as it were, the pathological condition of the organs he is examining. Dr. Loewenberg has hit upon the original idea of including plentiful photographs of pathological specimens, so that the reader can take in the physical signs, the scientific explanation of those signs, and the pathological condition they represent almost at a glance.

The most important sections in the book are on the respiratory and cardio-vascular systems, but the whole field of diagnosis is covered from the initial chapters on history-taking and general inspection right through to radiography, a special chapter on which has been written by Dr. L. Solis-Cohen. The section on the physical signs of respiratory disease is an excellent one, and a good example of the thoroughness of the author's methods, for he sketches the history of percussion and auscultation, gives a very full account of the methods in use, and cleverly illustrates the why and wherefore of breath sounds and added sounds heard over the lungs. A good addition to the cardio-vascular section is a chapter on electrocardiography and tests for cardiac capacity, while the concluding chapter contains most useful information on physical examinations as applied to industry, life insurance, health preservation (dealing with periodic health examinations), and the detection of malingering. A chapter on the interpretation of laboratory findings deals with the assessment of results and not with the actual laboratory methods employed, and this is perhaps a weak spot in a book intended, as the author insists, for the general practitioner. At the same time, this section does give valuable aid by indicating how to estimate the value of laboratory reports. Altogether, this book of over a thousand pages is an excellent production, and a valuable contribution to the literature of clinical medicine.

GONORRHOEA.

THE flood of literature that came as a direct result of the increased incidence of venereal disease following the war shows no sign of abatement, and Dr. GEORGE ROBERTSON LIVERMORE, professor of urology, Medical Department, University of Tennessee, and Dr. EDWARD ARMIN SCHUMANN, associated professor of obstetrics, University of Pennsylvania, have added yet another to the many existing works on the subject of gonorrhoea. In this work[3] they deal with the diagnosis and treatment of gonorrhoea, both in the male and in the female, and their aim is to present, in a practical manner, the results of their own personal experience rather than to discuss methods advocated by other authorities. This way of handling the subject has its advantages, though some readers will note with surprise that forms of treatment which are recognized in other countries receive no mention—for example, the treatment of gonococcal cervicitis by means of diathermy. The most probable explanation of this particular omission is that the authors, having found diathermy of little use in cases of acute epididymitis, apparently decided that it was not likely to be of value in the treatment of cervicitis. But such omissions are bound to occur in any book that aims at being concise and practical. A method of treatment that is likely to strike the British expert as unusual is the use of an in-dwelling catheter in cases of acute prostatitis; surely this procedure must lead to an epidemic of epididymitis in the authors' practice. The work concludes with a chapter on granuloma inguinale, a disease seldom seen in this country, and, as a result, one that is almost always missed when it is met with. Few textbooks describe it, and the good account given in this work will certainly be of value. The illustrations and figures scattered throughout the text are excellent.

COLLOIDS IN BIOLOGY AND MEDICINE.

WE have much pleasure in welcoming the appearance of a fifth edition of Colloids in Biology and Medicine[4] by Professor H. BECHHOLD. The first edition, which appeared in 1911, was a pioneer work, for it dealt with the application to medicine of a new and rapidly developing science. A second edition appeared at the end of the war, and the author explains that in the next two editions only a partial revision was attempted. Hence the book now before us is the first edition in which post-war knowledge has been fully incorporated. The author has obviously put a large amount of work into the preparation of the new edition, and has brought together a great mass of new information. Perusal of the book suggests, indeed, the doubt whether the subject has not really outgrown the limits of a single volume. When this book was first written

[1] *Applied Pharmacology*. By A. J. Clark, M.C., B.A., M.D., F.R.C.P., Professor of Materia Medica and Pharmacology in the University of Edinburgh. Third edition. London: J. and A. Churchill. 1929. (Demy 8vo, pp. xi + 529; 65 illustrations. Price 15s.)

[2] *Diagnostic Methods and Interpretations in Internal Medicine*. By Samuel A. Loewenberg, M.D., F.A.C.P. Philadelphia: F. A. Davis Company. 1929. (6 × 9½, pp. xiii + 1032; 547 figures. 10 dollars net.)

[3] *Gonorrhoea and Kindred Affections*. By George Robertson Livermore, M.D., F.A.C.S., and Edward Armin Schumann, M.D., F.A.C.S. New York and London: D. Appleton and Co. 1929. (6½ × 10, pp. xvi + 257; 66 figures. 18s. net.)

[4] *Die Kolloide in Biologie und Medizin*. Von Professor Dr. H. Bechhold 5 völlig umgearbeitete Auflage. Dresden und Leipzig: T. Steinkopff. 1929. (6½ × 9, pp. xii + 585; 87 figures, 7 plates. M.32.)

colloidal chemistry was in its infancy, and only a few persons had studied the application of that science to the problems of medicine. Since then the great science of biochemistry has grown up, and the larger portion of it is concerned with problems of colloidal chemistry. Professor Bechhold has, however, the advantage of having studied this new science continuously since it started its rapid development, and he has succeeded in producing a clear and readable account from the vast amount of scattered evidence that exists regarding his subject.

NOTES ON BOOKS.

A REVISED edition of *Recent Advances in Surgery*[1] has been soon demanded, but Mr. W. H. OGILVIE has not been content to rest on his laurels. Sixty pages on cancer and radium treatment have been added, and they succeed in giving a clear picture of both technical and clinical problems. Cancer of the tongue is the despair of surgeons, and there has been no approach to the late Sir Henry Butlin's results of twenty or thirty years ago. Modern methods cannot yet compete with his success, but they are producing results which bear publication. Mr. Ogilvie holds the balance evenly, but he feels that team work between old-fashioned surgery and new-fashioned radium *therapy must blaze the trail if further success is to follow.* The rest of the book is little altered, but there are several new plates and figures, a few are omitted, and there is a general improvement in the reproduction of the remainder. The new volume is thirty-five pages longer than the old, and the disappearance of hydrocephalus will be lamented by few. We confidently expect further editions of this admirable book, and in response to the author's disarming request for criticisms we can only point out that Madame Curie spells her name with one "r," and that a few diagrams of the intraneural topography of the main nerve trunks of the limbs would be a very welcome addition.

Since its first appearance in 1900 the *American Illustrated Medical Dictionary*,[2] by Dr. NEWMAN DORLAND, has been revised fourteen times, and the present fifteenth edition has been completely re-edited by the editorial staff of the *Journal of the American Medical Association*, under the direction of Dr. Morris Fishbein. By this new collaboration the dictionary has received the most thorough revision of its long career, and several thousand terms noted in the most recent medical literature have been added. The editors have throughout followed the official nomenclatures of the American Chemical Society, the Council on Physical Therapy, the Council on Pharmacy and Chemistry, the Association of Pathologists and Bacteriologists, the American Radiological Society, and similar bodies. Many illustrations have been added, and it may be said that the new edition fully justifies the great amount of work that has evidently been devoted to its preparation.

We have received a copy of the first volume of *Archivos da Fundaçao Gaffrée e Guinle*, published at Rio de Janeiro by a committee consisting of Professors Carlos Chagas and E. Rabello and Dr. G. da Moura Costa. The volume contains thirty-two papers which have been published elsewhere and deal mainly with various aspects of syphilis, certain nervous diseases, and laboratory methods.

[1] *Recent Advances in Surgery.* By W. Heneage Ogilvie, M.D., M.Ch.Oxon., F.R.C.S.Eng. Second edition. London: J. and A. Churchill. 1929. (5½ × 8½, pp. vii + 495; 115 figures. 15s. net.)

[2] *The American Illustrated Medical Dictionary.* By W. A. Newman Dorland, M.D., F.A.C.S. Fifteenth edition, revised and enlarged. Philadelphia and London: W. B. Saunders Company. 1929. (Med. 8vo, pp. 1,428; illustrated. 35s. plain; with thumb index 37s. 6d.)

PREPARATIONS AND APPLIANCES.

AN ORTHOPAEDIC OPERATION TABLE.

MR. B. WHITCHURCH HOWELL, F.R.C.S. (London, W.), writes:

The table here described was invented by me some years ago as the result of dissatisfaction with orthopaedic tables which are not adjustable in height. In it are embodied the ideas of other tables, with the following special features:

1. Oil pump base.
2. Pelvic rests, and extension apparatus for fractures and the application of plaster-of-Paris.
3. Torticollis rest for neck and shoulder operations, and the application of plaster-of-Paris.
4. Side tables for the operations on the upper limb.
5. Monel metal top, requiring no polishing, but soap and water only for washing.

By means of the lever L the table is made to rise or fall in sections so that it may be used for the application of plaster-of-Paris to fractures of the lower limbs.

The torticollis rest, indicated by T in Fig. 3 (top right-hand corner), was devised to facilitate the application of plaster-of-Paris to the head, neck, and shoulders immediately after the division of the sterno-mastoid tendon, as described in my paper on the treatment of torticollis read before the Orthopaedic

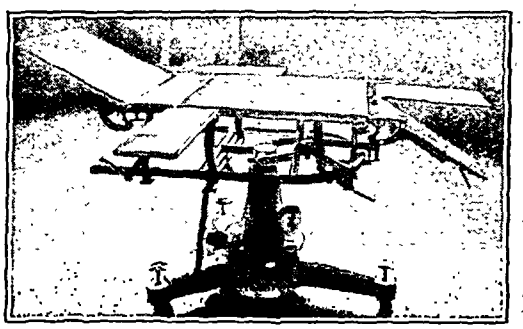

FIG. 1.

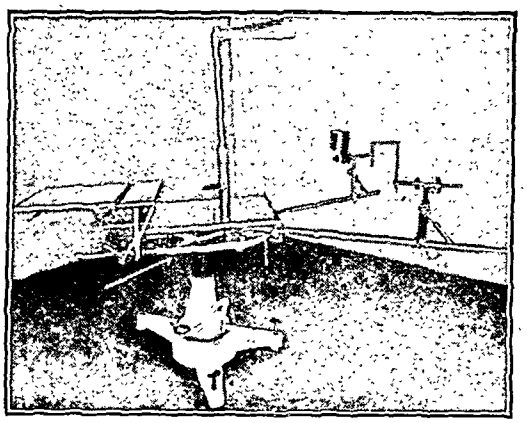

FIG. 2.

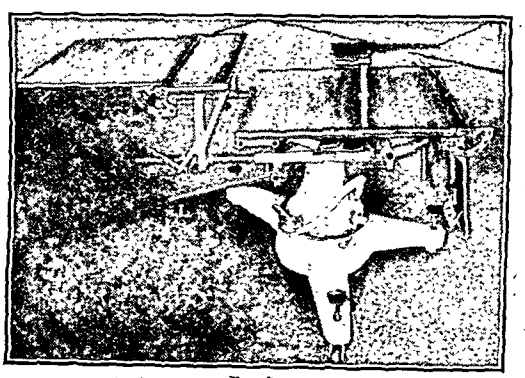

FIG. 3.

Section of the British Medical Association at Manchester in July last, which is published at page 714. Since that date several minor improvements have been made.

The photographs show the method of its working. It is manufactured by Messrs. J. H. Montague, of 69, New Bond Street, W.1, to whose courtesy and enthusiasm much of the success of the table is due.

AN INEXPENSIVE STOP-WATCH.

Medical practitioners, laboratory workers, and nurses may be glad to hear of a very inexpensive stop-watch which should suffice for everyday requirements. The centre seconds hand, which makes a complete revolution every minute over a scale graduated in fifths of a second, can be stopped or started at will by sliding a small projection on the outer rim. Apart from this mechanism the watch is an ordinary pocket timepiece with lever movement. The price is 7s. 6d., and other patterns with dig-back action are supplied at correspondingly low cost by the same firm. Messrs. A. Arnold and Co., 17, Elmcroft Avenue, Golders Green, N.W.11.

THE CAMPAIGN AGAINST TUBERCULOSIS.

CONFERENCE IN NEWCASTLE.

THE fifteenth annual conference of the National Association for the Prevention of Tuberculosis was opened in Newcastle-on-Tyne, on October 10th, under the presidency of Sir ROBERT PHILIP, vice-chairman of the council of the association, in the absence of Sir Arthur Stanley, the president.

A SURVEY OF TUBERCULOSIS ON TYNESIDE.

During the years 1925 to 1928 an attempt was made to measure and analyse the chief conditions affecting the welfare of the inhabitants of the industrial towns on the River Tyne. The method employed was the assembling and interpretation of existing data; there was no house-to-house visitation, and the survey was not made primarily by medical practitioners, though the assistance and advice of these was obtained. Mr. HENRY A. MESS, Ph.D., the director of the Tyneside Council of Social Service, was in charge of the work, and opened the conference of the National Association by reporting the findings with regard to tuberculosis. He stated that in all save two of the thirteen towns concerned the death rates from pulmonary tuberculosis for the quinquennium 1921 to 1925 had exceeded that for England and Wales for the same period. In nine this excess was 30 per cent. or more, and in the worst town it was almost exactly 100 per cent.; in twelve of the thirteen towns the death rate was in excess of that for England and Wales by at least 34 per cent., and in the worst town the rate was almost exactly three times that for the whole country. He admitted that application of the process of standardization for age and sex would probably modify these figures favourably for the Tyneside area, but, even so, the huge difference between the local and the national death rates would not disappear. The Tyneside area had suffered more than elsewhere owing to the intense industrial depression which had prevailed, and there had also been a high incidence of the respiratory diseases generally in this part of the country. Roughly, one-half of all the deaths from tuberculosis had occurred in persons under the age of 25, but no special occupational factor seemed to be concerned. There had, however, been obviously some influence at work operating unfavourably on the young, and on women, and with special strength in the north-east coast area. Tuberculosis authorities should give the most careful attention to the case of young women between the ages of 15 to 25. The speaker pointed out that the Tyneside towns were among the most overcrowded in England and Wales; the homes were generally small, and, except in the two middle-class suburbs, the percentage of persons living more than two to a room exceeded 30 everywhere, and in two of the towns was over 40. He had little doubt that the 42 per cent. of overcrowding in Jarrow had a direct relation to the 2 per 1,000 tuberculosis death rate in that town; this could not be the main factor, since two areas within the scope of the survey had very bad housing figures with quite good tuberculosis figures. Moreover, the pit villages and mining towns in the county of Durham had, as a rule, remarkably low tuberculosis death rates in spite of very bad housing conditions. Though it was a mistake to emphasize too much the effect of overcrowding on the incidence of tuberculosis, it could not be denied that, when from other causes tuberculosis had established its hold on an area, overcrowding became a factor of great importance by increasing the chances of infection, since there was little possibility of effective isolation. Tyneside was predominantly a shipping area, and this industry was one of those most subject to violent fluctuations. It was probable that occasional high earnings blinded both employers and employed to the actual lowness of earnings over a period of years, and it was suggestive that the worst tuberculosis figures in the area studied were found in those towns with a great deal of casual labour. Early notification of pulmonary tuberculosis was still lamentably deficient, and this prejudiced its treatment and promoted its diffusion. At present an immense amount of money was being wasted in sending patients to sanatoriums for absurdly short periods of time. Early diagnosis depended essentially on the provision of adequate staffing, particularly of health visitors. The attack upon tuberculosis had to be made from many directions, which included housing schemes, smoke abatement, protection of the milk supply, and the adequate treatment of patients. More co-operation of the different authorities concerned was necessary, and greater efforts to improve personal habits, such as expectorating in public places.

Discussion of this paper was opened by Councillor JOHN BARKER, chairman of the Tuberculosis Committee, Newcastle-on-Tyne, who stated his conviction that one of the most serious adverse factors in the fight against tuberculosis was the lamentable ignorance of the community as regards the menace of this infection. Interest had been awakened by the educational activities of the National Association, but much remained to be done. There had been an appreciable fall in the mortality rate in the Tyneside towns, but many hundreds of people were still dying whose lives might have been preserved. Isolation in a properly equipped sanatorium was the only safe form of segregation for working people, and a new tuberculosis pavilion had recently been opened in the Walkergate Sanatorium, giving accommodation for forty-four extra beds. No sanatorium could be considered properly equipped in which there was not an efficient *x*-ray plant for diagnosis, and every up-to-date appliance in medicine; more beds for advanced cases were also necessary. Councillor Barker urged the National Association to bring to the notice of the Ministry of Health the desirability of imposing on local authorities a stricter obligation to provide adequate tuberculosis dispensaries, educational agencies, and institutional segregation. Regional advisory councils should be established in industrial districts to ensure complete co-ordination and co-operation between medical practitioners and laymen. The erection of new houses and the clearance of slums were valuable agencies, but greater care ought to be taken with regard to protecting food from all kinds of infection during preparation and distribution; more teaching as regards cleanliness was also desirable.

The discussion was continued by Dr. VEITCH CLARK, medical officer of health for Manchester, who emphasized the importance of providing financial assistance for the families of patients in institutions, and so lessening anxiety, which greatly reduced the effectiveness of antituberculosis treatment.

FACTORS IN THE PRODUCTION OF ADULT PULMONARY TUBERCULOSIS.

Dr. EDOUARD RIST read a paper in which he discussed the causes of the appearance of pulmonary tuberculosis in the adult. Now that the old theories of constitutional or hereditary predisposition had been abandoned it was being recognized that the development of pulmonary tuberculosis in an adult person implied the occurrence of a first infection during childhood. This was usually succeeded by a period of years during which the patient remained healthy and apparently immune; he then suddenly showed signs of tuberculosis, which seemed to imply reinfection. The conditions of civilized life were far from healthy, involving as they did irregularities of diet, lack of exercise, and too great an amount of time spent indoors; if these could be rectified tuberculosis would die out. There were probably other factors which it would be the task of future investigators to discover.

Dr. C. G. R. GOODWIN, medical superintendent of the Newcastle-on-Tyne Sanatorium at Barrasford, emphasized the point that infection with the tubercle bacillus, though an essential factor, was not the sole cause of the production of manifest pulmonary tuberculosis in adults. Positive reactions to the tuberculin test were given by 90 per cent. of the general population in apparently good health, indicating that such infection was present; and in about the same percentage of bodies submitted to post-mortem examinations definite evidence was obtained of tuberculous infection, even though the signs and symptoms of it had never been apparent during life. In the case of patients entering the Barrasford Sanatorium it was most unusual to find any history of direct contact with consumptives, and the probability of recent infection was small. Dr. Goodwin concluded, therefore, that debilitating conditions, such as those inseparable from bad housing, were primarily responsible for a large proportion of the adult cases coming under treatment. In slum areas there were present all the conditions which produced debility, and when several adult members of the household showed signs and symptoms of tuberculosis within short periods, probably the cause was that they were all subjected to some adverse environmental conditions, rather than that actual disease had spread from one to another. Many cases of so-called influenza were really febrile manifestations of pulmonary tuberculosis, and injury, such as a blow on the chest, was another undoubted factor. Chronic alcoholism did not seem to be a real cause of tuberculosis, but the associated lack of sleep, inadequacy of nutrition, exposure, and similar debilitating conditions, contributed to such a loss of vitality as might allow the disease to become manifest. Dr. Goodwin assigned special importance to the influence of chronic fatigue as a factor, and gave examples of how the continuance of hard physical and mental work during the day and the evenings was particularly injurious. He was convinced that such fatigue—whether mental or physical—was one of the commonest causes of the reactivation in adult life of an infection contracted in childhood: there was always a definite fall in the body weight, and, therefore, regular periodical weighing was desirable, since in this way early diagnosis became possible.

Sir THOMAS OLIVER read a paper dealing with the factors producing adult pulmonary tuberculosis viewed from the industrial side; an abstract of it was published in our columns on October 12th (p. 674).

OTHER PAPERS.

The second day of the conference was devoted to short papers and discussions. Dr. A. H. MACPHERSON, medical superintendent of Burrow Hill Sanatorium Colony, described the scheme

which combines treatment with technical education in the case of youths between the ages of 14 and 19. We have previously called attention to the valuable work of this institution, in our columns of March 23rd (p. 570). Dr. WILLIAM BRAND submitted a scheme of national propaganda with regard to tuberculosis. Reference was made to Dr. Brand's proposals in the *Journal* of June 22nd (p. 1134). Dr. FERGUS HEWAT emphasized the value of providing instruction in tuberculosis for medical students, and gave details of the course arranged in the final year at Edinburgh. Dr. W. H. DICKINSON dealt with the importance of providing systematic training for tuberculosis officers. He believed that a period of general practice was necessary as a preliminary, and this might well be followed by the holding of a junior appointment in some department of the public health service other than tuberculosis, particularly if it was possible to combine with this a course of study for the D.P.H. Subsequently an appointment should be held in a large and well-equipped sanatorium for at least six months, and some instruction in non-pulmonary tuberculosis should be obtained. Mr. WILLIAM GUY, dean of the Dental Hospital and School in Edinburgh, read a practical paper on dentistry in relation to tuberculosis.

ALCOHOL AS AN ECONOMIC FACTOR.

NORMAN KERR LECTURE BY SIR JOSIAH STAMP.

THE thirteenth Norman Kerr Memorial Lecture, under the auspices of the Society for the Study of Inebriety, was delivered by Sir Josiah Stamp in the Great Hall of the British Medical Association House on October 8th. Mr. W. MCADAM ECCLES, F.R.C.S., president of the society, was in the chair, and the large audience included many well-known medical men and women.

Sir JOSIAH STAMP, who remarked that his written lecture was three times as long as his oral one, entered upon a brilliant analysis of the economic effects of alcohol production and consumption. He evidently assumed that his audience had a mastery of economics equal to his own, and rapidly and summarily placed one economic proposition after another before them, so that when at length he reached some comparatively simple and understandable conclusion they felt rather like those who watched Horatius breasting the Tiber, "when above the surges they saw his crest appear." He began by attempting a classification of the economic differences which must exist between the present state of affairs in which alcohol was freely partaken and an ideal condition in which alcohol was entirely absent. He divided the effects into four grades: (1) changes in production and employment involved by the removal of the demand for alcohol and the production of other commodities and services in its place; (2) changes in production resulting from changes in the producer consequent upon abstinence, these including the effects on efficiency of output, absenteeism, and accident rates; (3) the social costs of alcohol, as in the prevention of crime and the treatment of disease; and (4) influences on character, morals, happiness, and family life, promoted or retarded by alcohol. With regard to statistics and illustrations from the interesting social experiment proceeding in the United States, he gave certain reasons why no rough-and-ready conclusions as to American prohibition should be adopted. Prohibition notwithstanding, there was no complete absence of alcohol in that country, a circumstance which had brought certain specific evils in its train; again, the records of improved social and economic conditions there involved a combination of many causes, and the assignment of particular effects was very difficult; and, finally, a good proportion of statistics were drawn from polemical literature, although it was true that the amount of work on scientific disinterested lines was steadily growing.

In dealing with the effect of alcohol or its absence upon the efficiency of the working output, the lecturer said that he had taken all the available records of physiological experiments, some twenty-six in number, covering physical and mental reactions, accuracy, and quickness, made by medical men and physiologists. These included the most recent ergographic studies. Before they were applied to industry as a whole, many reservations had to be made, but he thought the results were consistent with a minimum estimate of 5 per cent. gain in efficiency as a result of absence of alcohol, but that they would not themselves support a higher estimate than 10 per cent. A summary of experience in America from various questionaries, however, had indicated a difference of between 10 and 15 per cent. He had himself questioned many manufacturers in the United States, and the figure generally given for increased efficiency was between 10 and 20 per cent. On the incidence of industrial accidents the influence of alcohol was very indeterminate. He quoted a United States authority who for twelve years had been examining the records: "I know that alcohol is a serious factor in accident occurrence, but to demonstrate its seriousness is very difficult, and I have given up the attempt."

With regard to the economic costs of crime caused by drink, Sir Josiah Stamp pointed out here, again, the lack of all value in the usual statistics, even those quoted in the well-known work of Horsley and Sturge. It was customary to say that of the total convictions a certain proportion were for drunkenness, but most needed was information—which appeared never to be given—about the effect of alcohol on the incidence and nature of the other crimes and misdemeanours. Again, the costs of poverty due to drink were usually confused with the costs of charity and maintenance, which did not represent a loss of wealth, but only a transfer. He thought, however, that the available statistics justified an estimate of over 20 per cent. of poverty as directly attributable to alcohol. The total out-of-pocket social costs of alcohol in sickness, crime, and accident, borne out of tax funds—a cost which would not be incurred but for alcohol consumption—lay between 25 and 50 millions, but if the figure was to include voluntary effort in the shape of charity and hospitals, it would be considerably greater. He also pointed out that in so far as the absence of alcohol had a tendency to lengthen life, this was an economic gain only in proportion as it diminished the risk of death during the working period; in so far as it lengthened life after 65 it was an economic loss, amply compensated for, no doubt, by humanitarian and sentimental gain. In other words, it was no economic loss to the State, but quite the reverse, if a man having finished his working career at the lower age, died at 70 instead of 80.

Sir Josiah Stamp entered into many other interesting discussions, including the effect of the diversion of the family income from alcohol to milk, and contrasted whatever might be the satisfactions of alcohol for the parents with the benefits derived from the additional growth of the children due to increased milk consumption, not to speak of the advantages of better clothing and household amenities, house purchasing, and additional saving following upon the gain to the family exchequer if alcohol were no longer purchased. The lecturer's general conclusion, after an attempt to assess the various factors he had instanced at the beginning, was that the weight of evidence showed that the effect upon national economic welfare was not less than 8 per cent. nor more than 15 per cent.

At the close of the lecture Viscount Brentford, who was introduced by the chairman more familiarly as "Jix," moved a vote of thanks to Sir Josiah Stamp. He mentioned that he was shortly celebrating his fiftieth anniversary as a pledged total abstainer. Confessing that after such a lecture his brain was in a whirl, he said that, so far as he could see, three conclusions were to be drawn from the arguments Sir Josiah Stamp had advanced—namely, that the workman who was an abstainer was more efficient than the workman who took alcohol, even to a moderate amount; that the amount of money spent on the consumption of alcohol could be better expended on commodities and services more useful to the community; and, finally, that the earlier the old-age pensioner died the better economically for the nation, though it was true that the lecturer had intentionally disregarded sentimental considerations, which, of course, far outweighed any economic ones in this connexion.

After the vote of thanks had been seconded by Sir THOMAS BARLOW and carried, the CHAIRMAN announced that the next Norman Kerr Memorial Lecture, in 1931, would be delivered by Viscount Brentford, who had elected to speak on "How the alcohol question concerns the duties of the Home Office."

MOTOR CARS FOR 1930.

THE OLYMPIA SHOW.

[From our Motoring Correspondent.]

The visitor to the annual motor show at Olympia, which opened on October 17th, cannot fail to be impressed by the large variety of cars and the wide range of prices. While popular-priced cars are admittedly excellent value for money they are bound in some respects to be inferior to those costing more. Saving may be effected at the expense of paintwork and upholstery, to mention only two features having an interest for medical motorists. The doctor's car has to be used all the year round and in all varieties of weather, and the paintwork and upholstery must therefore be of very good quality if they are not to lose their smart appearance. It is evident that the doctor in buying a car would be well advised to give due weight to factors other than price before making his final choice.

A Technical Survey.

An interesting summary, prepared by the *Autocar*, of the tendencies in motor chassis design and construction, as shown by the 1930 models, largely bears out the views expressed in these columns last week. Thus, it shows that of the wide range of British and foreign cars now on the market in this country more than half—52.5 per cent., to give the exact proportion—are of the six-cylinder type, as against only 49.6 per cent. a year ago. On the other hand, those equipped with four-cylinder engines, which until about 1925–26 were in the majority, have fallen during the past twelve months from 34.6 per cent. to only 26.8 per cent. The increasing vogue of eight-cylinder vehicles is also shown by the fact that they now represent 18.3 per cent. of the total as compared with but 14.6 per cent. twelve months ago. From an examination of the cars at Olympia it is evident that the change over from magneto to coil ignition, referred to last week, is even more general than at first appeared. As a matter of fact the position during the past year has been entirely reversed; magneto ignition now takes second place to ignition by coil and distributor, the former having declined from 47.3 per cent. to only 32.3 per cent., while the coil form has advanced from 45.4 per cent. to 60 per cent. Another notable alteration in engine practice is in connexion with the water cooling, the ratio of cars with pump circulation having advanced from 67.1 per cent. to 72.8 per cent., that of cars depending on the thermo-siphon principle of circulation having fallen from 32.2 per cent. to 25.7 per cent.

Marked changes have also been effected in the transmission details of chassis. Clutches of the disc or plate type are now almost universally employed; the once popular cone type is now very rare, being found on only 2.3 per cent. of the cars. Unit construction of the engine and gearbox continues to increase in favour, the proportions of "units" and separate gearboxes being now about 83 per cent. to 16 per cent. Reference was made last week to the tendency to provide gearboxes with four instead of three speeds. At the same time, the central gear change is not quite as popular as it was, the proportion having fallen from 66.8 per cent. to 63 per cent.; on the other hand, the proportion of cars with right-hand change has progressed from 31.8 to 35 per cent. Another change is in connexion with propeller shafts; the open type is this year more general than the enclosed variety, the torque of the back axle being now taken up through the springs. An examination of the cars at the show also corroborates the impression gained from the advance information that wire wheels are now the most popular, over 60 per cent. of all 1930 cars having them, as against 47 per cent. during the past year. Curiously enough, it is the ordinary wood- or steel-spoked variety that has lost ground, while the proportion of cars with disc wheels remains about the same.

The Popular Morris Cars.

The well-known Morris cars maintain their popularity as well with doctors as with the general motoring public, and hence a few details of this company's 1930 programme may be given. The Morris Minor, introduced a year ago, has proved a very successful model, providing as it does a most useful little car at a very low price. It is not surprising, therefore, to find that it is being continued with but a few detailed improvements. Fitted with an engine having a tax rating of only 8 h.p., and using only one gallon of fuel for every 40–50 miles, it has shown itself to be a "go anywhere" car. Similarly, too, the 11.9 h.p. Morris-Cowley has only been changed in detail. Notable additions to both the Minor and Cowley range is a saloon with a folding head, providing the advantage of a partially open car in fine weather. The price of the larger of the two vehicles is £200.

The chief departure of the Morris Company for next year is the replacement of the Morris-Oxford 14–28 h.p. four-cylinder cars with an entirely new range of six-cylinder vehicles rated at 15 h.p. The new cars have several novel features. The engines have an air cleaner incorporated in the casing of the cylinder head, which collects any fumes from the crank-case and prevents them from entering the body of the car; the radiators are provided with shutters automatically controlled by a thermostat to maintain the water at the most efficient temperature; brakes are of the Lockheed hydraulic variety, while the springs are fitted with hydraulic shock absorbers. Following a modern tendency, the control switches of the lamps, as well as the throttle and ignition levers, are neatly grouped in a small circular casing on the steering wheel. The new model is being built in four styles—an open four-seater, a coupé and a coach-built saloon, both with sliding head, and a fabric saloon; the prices range from £275 to £299.

Another Morris "six" designed for the use of motorists desiring a car of greater power is the "Isis" model, the engine of which is rated at 18 h.p. The new "Fifteen," however, is well able to meet all ordinary requirements, and is likely to prove the most popular of the Morris range during the coming year. Finally, it may be mentioned that all these cars, from the Minor to the Isis, are now fitted with Triplex safety glass windscreens and windows, and that all bright parts are chromium-plated.

The Citroën Cars.

Another make of cars very popular among doctors is the Citroën. Attention is now being centred on two models—a 13-30 h.p. four-cylinder and a six-cylinder of 2½ litre capacity. The smaller vehicle, the prices of which range from £250 to £305, has only been altered in detail. On the other hand, the "six" has been considerably modified with the object of securing better performance and durability. Among the numerous improvements are the adoption of a new design of clutch and gearbox, hydraulic shock absorbers, a hand-operated brake on the transmission, a new and more powerful starter, a vibration damper on the engine crankshaft, and oilless spring shackles. The track has also been increased to enable the bodies to be widened, while other coachwork improvements include new colour schemes, better quality trimmings, arm rests, roof ventilators, and chromium-plated bright parts. The Citroën "six" is being made in three grades—standard, "safety," and "sports"—with prices varying between £298 and £450.

Armstrong-Siddeley and Austin Cars.

The Armstrong-Siddeley Company, which was one of the first to introduce a light six-cylinder car at a popular price, has now ceased to manufacture the 14 h.p. four-cylinder car in order to concentrate on "sixes," of which, in addition to the 12 h.p., there are 15, 20, and 30 h.p. models. The improvements for 1930 include a new labour-saving finish for the radiator, chromium plating, and central "one-shot" chassis lubrication. On certain models unsplinterable glass windscreens and anti-glare headlamp control have been adopted. The firm's special "self-changing" silent four-speed gearbox is being continued as an extra on the 20 and 30 h.p. models.

A firm which for some time has given up the practice of bringing out different models each year, but is incorporating improvements as these are found necessary or possible, is the Austin Motor Co., Ltd. Four models are produced—7 and 12 h.p. four-cylinder, and 16 and 20 h.p. six-cylinder—it being found that with this range the requirements of the majority of motor users can be met. A considerable number of doctors have found in the Austin Seven a vehicle which, though diminutive, is well suited to their practice; many are, and will continue to be, more conveniently served by the "Twelve." A number of users have, however, changed over during the past year from the 12 h.p. four-cylinder to the 16 h.p. "six," and, despite its slight extra cost, report very highly of its smooth running and general satisfactoriness. Among the recent detail improvements are the chromium plating of the external bright parts, and the adoption of new wings of larger, dome design. The 12 h.p. and 16 h.p. models are fitted with central gear change, the lever of which has been lightened and lengthened with the object of providing more convenient operation. All the models, with the exception of the "Seven," are now fitted with Silentbloc oilless spring shackles, which not only eliminate a number of greasing points, but add considerably to the riding comfort. The throttle and ignition levers are now neatly placed at the head of the steering column. Additional new details on the 16-h.p. and 20-h.p. cars include Biflex headlamps with electrically controlled dip and switch reflector equipment.

The Singer Series.

Another firm which has dropped its medium-power four-cylinder car in favour of a light "six" is Singer and Co., Ltd. The Singer Junior "four" is, however, retained, and has been improved in detail, with prices ranging from £135 to £165. Chief interest lies in the new "six," which, as a coachbuilt saloon, is listed at £275, making it one of the cheapest six-cylinder cars on the market. The engine is of the side-valve type, with a £16 tax rating. Coil ignition with automatic advance and retard is fitted, and the crankshaft runs on four main bearings. The three-speed gearbox is centrally controlled. The specification also includes chromium plating, Triplex safety glass, bumpers, and real leather upholstery. For those requiring a more powerful car at the same taxation rating, there is the Singer Super-six, which has a long-stroke engine with a cylinder capacity of 1,920 c.cm. A four-speed gearbox is also provided on this model, which is available in either coupé or saloon form at £350.

Hillman and Humber Cars.

The Hillman and Humber Companies, although still carried on as entirely separate undertakings, now work in close association. Hillmans are continuing to concentrate their energies on only two types of chassis—a 14 h.p. four-cylinder and a 20 h.p. "straight eight." The latter, with prices ranging from £430 to £510, constitute the cheapest of the British-built eight-cylinder vehicles, but they compare favourably with others from the points of appearance, performance, smoothness of operation, and general comfort. Many detailed improvements have been introduced into both models, including the Silentbloc oilless spring shackle bushes. If the Hillman cars have only been modified in detail, the Humber series have undergone radical changes. Their range now includes 9–28 h.p. four-cylinder, 16–50 h.p. and 20–65 h.p. six-cylinder, and two entirely new 24–73 h.p. "sixes," one known as the "Snipe" and the other as the "Pullman." The prices vary between £240 and—for a cabriolet de ville—£1,095. Chief interest in the new series lies in the "Snipe" vehicles, the saloon of which is listed at £535. There are many interesting features in the new models, notably an improved four-speed gearbox which, owing to the use of helical gear wheels, provides a third speed as silent as the fourth.

Stars and Triumphs.

In the earlier motoring days there were many doctors who found Star cars very reliable productions. For the past few years, while maintaining their reputation in this respect, the Star Motor Co., Ltd., have concentrated their attention on somewhat high-powered cars of 18–50 and 20–60 h.p., both equipped with six-cylinder engines. In this case also only detailed changes have been found necessary, these relating chiefly to the clutch, brakes, and steering gear. A new type of radiator has been adopted, as has also chromium plating of the bright parts, while sliding roofs can now be provided on all closed cars.

So extensive has been the demand for the "baby" car known as the Triumph Super-seven that the Triumph Company is now practically concentrating production on this one model, which it supplies, however, in a wide range of attractive bodywork. Little or no alteration has been made in the chassis details, what changes there are being in the external appearance, and arising chiefly from the adoption of a ribbon radiator—in other words, one having thin metal edges. Chromium plating of the bright metal parts, and safety glass for the windscreens—and for the windows on most models—have also been standardized. Several styles of bodywork are available, among these being a two-seated coupé with fixed head, a de luxe fabric saloon, and a coach-built saloon, the latter having been remodelled on fashionable lines.

Notable Motor Bodywork.

As usual, the annexe to the main hall is devoted to a display of cars fitted with special bodywork, all striking examples of the carriage-builder's art. The majority of doctors nowadays are content to choose one or other form of the standard bodywork supplied by car manufacturers. Medical men, however, who do not mind the extra cost involved can exercise choice, both as regards any particular chassis and the design and finish of the body.

It is impossible to refer to all the vehicles in the carriage-building section, many of which, indeed, are too large and elaborate, as well as too costly, for the ordinary doctor's use. Among exhibits to which special attention may be drawn, however, are those of Gordon England, Ltd., and Mann Egerton and Co., Ltd. The last-named firm has for some years past given special attention to the construction of doctors' cars. For purely professional use Messrs. Mann Egerton recommend the coupé type, but for those requiring a vehicle that can also be used for recreation they have produced what they term the "M.E." all-purpose coupé-cabriolet. This body, while retaining the characteristic appearance of the coupé, provides, by means of collapsible occasional seats, accommodation for four passengers inside; it is also so constructed that the boot at the rear can be fitted to take a dickey seat for two more. A further development of the main idea is shown on an Austin 16 h.p. chassis, the body in this case having, in addition to the two front seats, a wide well-upholstered single seat behind the driver capable of seating three, so accommodating altogether five persons inside. The really novel feature of this car is the four-position roof. When the roof is completely closed the vehicle has the appearance of a normal coupé, but by simple adjustments every conceivable opening can be obtained—that is, the roof only, or the rear quarter only, or the roof and rear quarter together, the two latter giving the equivalent of a completely open car. It is the work of a few seconds only to secure any of the different positions.

A Useful Buyers' Guide.

Last week's issue (October 11th) of the *Autocar* as usual included the Annual Buyers' Guide, a feature which is always appreciated at the time of the show. The guide is intended to help intending purchasers in their choice of a new car, and comprises alphabetically arranged tables of all 1930 models, British and foreign, on the market in this country, with their full specifications, principal dimensions, annual tax and weight, together with the prices of the different vehicles in chassis, saloon, and open-tourer forms.

Next week we propose to deal briefly with other cars exhibited, and also to draw attention to some of the more interesting exhibits in the galleries. It may be well to remind readers that the show will be open daily from 10 a.m. to 10 p.m. until Saturday, October 26th. The charge for admission on Fridays and Saturdays is 2s. 6d., and on all other days 5s.

C. J. W.

British Medical Journal.

SATURDAY, OCTOBER 19TH, 1929.

ABDOMINAL PAIN.

That physicians and surgeons, both individually and in conference, should actively concern themselves with the study of pain is in the nature of things. Among the manifestations of disease pain has a conspicuous place, and it is one of the most frequent of the discomforts that drive the sufferer to solicit medical advice and to demand succour and relief. Indeed, not a few persons would agree that one of the main functions of the doctor is to understand what any given pain means, what is the cause of it, by what means it may be promptly suppressed, and how further attacks may be prevented. Hence the layman will hardly be surprised to know that pain is a subject much discussed by doctors, and his only comment will probably be that it is high time they knew all about it. If, however, attention is given to two papers read at the recent meeting of the British Medical Association at Manchester, and printed in the opening pages of our present issue, any notion that pain is a very direct and simple issue will not long survive. The title of the discussion may appear engagingly straightforward, but abdominal pain, as revealed in contributions made by those most competent to deal with it, is found to be associated with problems both numerous and difficult, and while some of these are problems of practical clinical interpretation, others have their roots in anatomical structure and in the physiology of many parts of the nervous system. Not that the two groups of questions are separate and distinct: on the contrary, they have intimate associations one with another, and doubtless it was an appreciation of this relationship which determined that the contributions of physicians and surgeons should be brought on to a common platform with those of physiologists and biochemists.

From several quarters in recent times active co-operation of the physiologist with the clinician has been advocated; and certainly the interpretation and explanation of pain—its causes, the nervous pathways of its travel, the anatomical structures involved—would seem to supply a platform on which doctrinal physiology and clinical experience can meet with advantage. While the principal aim of any such discussion may be to make pain "a valuable asset for purposes of diagnosis," the benefit may well be a mutual one, for on not a few occasions medicine and surgery have done much to help to solve some of the problems which perplex the physiologist.

If the joint meeting of the two Sections had a well-chosen subject, it was fortunate also in the contributors to the discussion. Dr. Charles H. Mayo and Sir Farquhar Buzzard, who introduced the debate, not only presented the subject in its surgical and medical aspects respectively, but each showed himself to be fully aware of the scientific studies of pain to which both physicians and physiologists have alike contributed, and abundantly competent to discuss these. One clinical topic in particular they found in common —namely, the gastric crises of tabes dorsalis—and each makes a serviceable comment. The physician describes features of the attack which he maintains mark it out quite characteristically from seizures which may need abdominal section, and he does well to remind us that absence of the knee-jerks is not an essential part of the picture. The surgeon submits an ingenious analysis and grouping of symptoms as these give reason to believe that the splanchnic nerves, or the vagi, or the phrenic nerves are involved; and recalling the attempts to relieve angina pectoris by section of some of the branches of the cervical sympathetic, he notes the possibility of controlling hyperacidity and pylorospasm by section of one or more branches of the vagi. Two other observations of interest, each with an obvious physiological relation, may be quoted: one a doubt that the vagus nerves ever have anything to do with the transmission of pain from the upper abdomen; and another that, in view of the association of pain in the right shoulder and neck in diseases of the liver and gall-bladder, it is probable that the phrenic nerve is a medium for the passage of painful stimuli.

On the strictly practical plane Sir Farquhar Buzzard contributes a number of memoranda of great value, both as aids to diagnosis and as warnings against a too ready conclusion that abdominal pain wanting an obvious cause must needs be met by surgery. The simulation of the pain of appendicitis by right basal pneumonia or infarction is not uncommon, and most house-physicians have had an opportunity of observing it. Less frequent is the epigastric pain accompanied by vomiting and collapse seen in coronary thrombosis —a clinical picture not unlike that of perforated gastric ulcer. Among the rare causes of abdominal pain described during the discussion are "angina abdominalis" associated with atheroma of the abdominal aorta, painful paroxysmal intestinal spasm in anxiety states, and puncture of an artery, which, it is said, "will cause dull pain of a peculiarly unbearable type," with perhaps reflex sweating and nausea (C. H. Mayo).

Among the theoretical issues debated were inevitably such questions as the late James Mackenzie's claim that pain is felt, not in the viscera, but in the overlying structures, and the same author's doctrines of viscero-sensory and viscero-motor reflexes. These teachings have their critics, and on the first of them Dr. Mayo says that because certain viscera "appear insensitive to cutting and pinching" this does not prove that they are incapable of giving rise to pain, as it may be that "there is no physiological necessity for these organs to respond painfully to the type of stimulus used." It would have been of interest had some critical physiologist offered an opinion on this doctrine. Much discussion centred round the relation between spasm of unstriped muscle and abdominal pain. There was general agreement that undue contraction in the wall of a hollow viscus causes pain by pressure on the nerves in the visceral wall, and evidence was quoted to show that, similarly, abnormal distension led to pain by stretching of the nerves. Sir Farquhar Buzzard made a subtle point when he asked, Is the afferent impulse which arouses the muscular spasm in the wall of the ureter, in a case of impacted ureteral calculus, a painful impulse, or is the pain evoked only by the tension consequent on the muscular spasm?

The opening papers of the discussion at Manchester present the whole subject on a high scientific level. They show its intricacies and difficulties, and leave at points some room for differences of opinion. In them are no short cuts to a swift and certain diagnosis. But the study of them has value both in the field of thought

and in the field of practice. Abdominal pain is a frequent symptom, and its correct interpretation is, at least at times, of the highest moment. In the two papers we print there are substantial aids to this interpretation, and their authors deserve from the profession a cordial message of appreciation.

NEW LIGHT ON LIVER INTOXICATIONS.

SOME of the more recent work on the prevention and cure of liver intoxications is of great interest from a purely biochemical point of view, and may well prove to have a wide clinical application. The experiments of Mann and Magath with dehepatized dogs, carried out some years ago, emphasized the fact that one very important function of the liver is the maintenance of the blood sugar at a sufficiently high level. When frequent intravenous injections of glucose were given, the dehepatized dogs could be kept alive for several days, whereas without this treatment they showed severe hypoglycaemic symptoms and died in a very sort time. It had also been realized for some time that animals with good reserves of glycogen in their liver, for instance after feeding with adequate amounts of carbohydrate, were more resistant than those with depleted stores to agents liable to cause liver intoxication and atrophy.

To this very slender stock of knowledge Minot and his collaborators have now added several important facts. While investigating carbon tetrachloride poisoning in dogs, Minot[1] found (originally as the result of an accidental change in the stock dietaries) that animals which had been kept on a diet with a low calcium content were particularly susceptible to the poisonous effects of this drug. Moreover, they could be made very resistant even to large doses by feeding for a few days with a diet rich in calcium. The susceptible animals had gastro-intestinal symptoms and tetany-like convulsions, and at post-mortem examination showed severe central necrosis of the liver. Even after symptoms of poisoning appeared, however, the dogs could often be cured by repeated intravenous injections of calcium chloride. Minot and Cutler,[2] extending this work, showed that poisoning by guanidine compounds and by chloroform inhalation very much resembled that produced by carbon tetrachloride in susceptible animals, and that the guanidine content of the blood did in fact show a considerable rise in all three types of intoxication. Moreover, they believed that similar symptoms appeared in all at similar levels of blood guanidine. There was at the same time a serious fall in the blood sugar level—doubtless another sign of impaired liver function—and the authors received the impression that the severity of the intoxication bore a definite relationship to the severity of the hypoglycaemia. The artificial raising of the blood sugar level by intravenous injection of glucose was not, however, a very successful form of treatment, as the nervous symptoms were not cured, nor, as later experience showed, was it at all easy to maintain the required level by this means alone. On the other hand, when treatment by calcium injection was once more resorted to, it was found that this did, by some mechanism as yet unknown, raise the level of the blood sugar, and maintain it at a nearly normal value. By the simultaneous administration of calcium and glucose remarkable cures could be effected in severely intoxicated animals, provided that the severe and intractable intestinal haemorrhages which were sometimes a prominent symptom did not render a cure impossible.

A few clinical cases (not including any cases of chloroform poisoning) in which there was presumably impairment of liver function, and in which similar phenomena were observed, were treated on these lines with satisfactory results, except in those cases in which the liver condition was of very long standing. One case of acute catarrhal jaundice had a high blood guanidine and a very low blood sugar level (0.05 mg. per 100 c.cm.), and was much improved by putting on a meat-free diet rich in carbohydrate, accompanied by oral administration of calcium lactate. A baby which had had a congenital abnormality of the liver, and which eventually died of the accompanying digestive disturbances, also had a very low blood sugar level and a high blood guanidine level. Administration of glucose by the mouth raised the blood sugar level to 0.07 mg., but calcium medication was necessary to raise it above this and to prevent the occurrence of tetany. Post-mortem examination showed severe necrosis of the liver. Several cases of "eclampsia" and "pre-eclamptic toxaemia" were included in the series, and are of particular interest, as they show that calcium and glucose medication is a valuable form of treatment in these cases and causes considerable improvement of the symptoms. The blood sugar falls to 0.06 or 0.075 per cent. in pre-eclamptic conditions and as low as 0.05 or 0.04 per cent. before actual eclamptic convulsions.

This work is obviously highly suggestive, and demands further clinical investigation; while to the biochemist the explanation of the pronounced effect of the administration of calcium upon the carbohydrate metabolism offers an intriguing problem.

DISTRIBUTION OF RADIUM.

AT a meeting of the Radium Commission, held on October 11th, with Lord Lee of Fareham in the chair, further consideration was given to the question of the disposition of the four-gram "bomb," the loan of which has been secured by the National Radium Trust for a period of three months from November 1st, with an option to purchase at the end of that time. Applications for the custody and use of this bomb having been invited from a selected list of hospitals with special experience of radium therapy, the various schemes submitted were examined, and, after careful consideration of all the questions involved, it was unanimously decided that the bomb should be entrusted provisionally to the authorities of the Westminster Hospital, subject to their acceptance of certain conditions and terms prescribed by the Commission. With regard to these, negotiations are proceeding between the Commission and the hospital authorities, and a further announcement will be made shortly. So far as the supply of national radium which will come under its control is concerned, the Commission's policy of allocation will be based upon the principle of concentration at a limited number of centres in Great Britain, to which patients will have to be brought for treatment. In its view, a smaller subdivision of the radium, in an attempt to satisfy the demands of the large number of hospitals, institutions, and individual medical practitioners who are submitting applications, will not be either feasible or desirable. The Commission hopes, however, that the limited supply of radium available may be supplemented by the distribution, under proper safeguards and conditions, of radon (radium emanation) prepared under its auspices. This aspect of the problem is receiving special consideration, as is also the question of fees to be charged for the loan or supply of

national radium or radon. It was further decided that any national radium sent out on loan should be fully insured, at the cost of the hospital or other institution to which it is entrusted. The Commission has succeeded in arranging specially favourable rates of premium which will make this charge a comparatively light one. All communications should be sent to the secretary, at 5, Adelphi Terrace, Strand, W.C.2.

THE PROVISION FOR CHRONIC DISEASE.

The success which has attended the attack on epidemic and acute disease has thrown into more prominent relief the prevalence of disease which is more chronic in character. The more advanced age to which a large proportion of the population lives emphasizes this. Some American statistics show that whereas sixty years ago chronic diseases caused only one-fifteenth of all deaths, they are to-day responsible for one-half. It is no wonder, then, that the attitude both of the medical profession and of the community towards chronic disease is changing, and that the problems to which it gives rise have become urgent. These problems, and the methods for dealing with them from the American standpoint, are admirably set out and discussed in a book entitled *The Challenge of Chronic Diseases*,[1] by Drs. Boas and Michelson, physicians to the Montefiore Hospital for Chronic Diseases. The volume is relatively short, but not a page is wasted, and, being the outcome of the authors' own experience, it teems with very practical suggestions. The writers say that "the book is designed for the layman who is interested in communal problems as well as for professional workers in the field of public relief. It is our hope that it may also serve as a modest handbook for those who are directly charged with the care of sufferers from chronic diseases." It is excellently suited for all these purposes and persons. Among patients suffering from chronic disease it is only the insane and the tuberculous who have been adequately catered for. A very large proportion of the others are being dealt with under the Elizabethan Poor Law and institutions, and, in America, under laws and in "almshouses" which have the same origin. Reform has proceeded even less far in America than in this country. The picture presented in this volume of the "almshouse" is, in general, appalling. "Poverty is the only common denominator of the inmates. In any almshouse we may find the well, the aged, the feeble-minded, the expectant mother, and the sick, not a few epileptics and insane and tuberculous." There is an increasing number of diseased occupants, yet they receive no medical care. In one with fifty inmates "there were patients with tuberculosis, far-advanced cancer, all types of heart disease, neurological conditions, one with a tumour of the brain, all languishing in bed with only an orderly to administer to their wants. The sole medical supervision was in the hands of a non-resident physician, who was required to visit every day for half an hour. When questioned as to their various ailments he replied, 'How should I know what's the matter with them: I guess most of them have asthma,' and for treatment the majority received a dose of asthma medicine." Nearly 40 per cent. of the almshouses have not more than ten inmates each; more than half accommodate only twenty-five. The superintendents are almost all illiterate, and in one case we read: "Superintendent is very low grade, and his wife, who is matron, is evidently a moron." While in our country we cannot match this picture, it must be admitted that many of our Poor Law institutions stand in need of reform. Of recent years improvement has been steady and great, and the hope is that this year's Local Government Act has brought us to the last stage. There is perhaps some danger that, in the rearrangements thus provided for, the chronic patient may receive less than his due. The prevalent desire seems to be to turn the transferred institution into a first-class hospital for general diseases. It would be salutary if at this stage administrators, lay governors, and medical staffs would read the book now under notice. In Great Britain those chronic patients who can be dealt with at home are provided for by means of old age pensions, health insurance, including medical attendance even when sickness and disablement benefit ceases, and nursing care, though this last is in need of systematization and extension. In America these things are not forthcoming, so the problem of such patients is urgent in many areas. For the rest, the medical, economic, and social factors rendering suitable hospital provision necessary are well stated by Drs. Boas and Michelson, and a useful division of those to be provided for is made into persons needing active medical care, those needing chiefly skilled nursing, and those needing only custodial care. The character of the institutional provision for all these is considered in detail, as well as the relation which such institution should bear to the hospital for more acute cases, and to the training of medical students and nurses. Suggestions of a very practical and valuable kind are made in these chapters, and, taken altogether, the book is to be commended to widespread consideration, both in this country and in that of its origin.

VENTILATION CONDITIONS.

Mr. R. C. Frederick has published the lecture which he delivered last March at a meeting of the South-Eastern Counties Section of the Institute of Chemistry on the investigation of normal and abnormal ventilation,[1] providing a concise and well-written account of the subject. He has studied the physiological literature and cites the chief authorities, but, being a chemist, he inclines, perhaps naturally, to belief in the old view that there is some injurious quality of the air in ill-ventilated and crowded rooms, quite apart from dust, microbic infection, and heat stagnation. There is always a tendency to fly to some mysterious unknown agent such as "deionization," which certain engineers in the United States of America are now discussing—men who advocate systems of mechanical ventilation with so-called "conditioned" air. There is not the least proof of any subtle poison being exhaled by human beings or of the ionization of the air having any influence in making open-window ventilation better and more stimulating than do mechanical methods which propel heated and conditioned air through ducts. Of first importance in the prevention of infection by microbes and of pollution of the respiratory membrane by dust are plenty of space and very free ventilation; there is also needed an abundance of cool air to stimulate the flow of blood through and secretion from the respiratory membrane. The latter carries the lysozyme, discovered by Flemming, which is potent in destroying microbes. Mr. Frederick, however, scarcely touches on this essential matter, though he comments fully on the equally important action of good ventilation in preventing body heat stagnation; furthermore, he does not discuss the advantages of exposure to cool clean air and light—in open-air schools, for example—as a means of stimulating health, restricting himself to the consideration of the ventilation of rooms. He deals very well with the question of the use of the percentage of carbonic acid as an index of ventilation, and with the psychological effect induced by confined hot places, which may be unbearable to the newcomer, but are little noticed by the workman inside, who has become acclimatized to working in this atmosphere.

FACTORS IN THE PRODUCTION OF BLACKWATER FEVER.

A controversy of considerable importance is given prominence in the June and July issues of the *Kenya and East African Medical Journal*. There has hitherto been a fairly general impression that quinine administration is one of the exciting causes of an attack of blackwater fever, and statements to this effect appeared in the paper by Professor D. B. Blacklock and Dr. G. Macdonald, on the mechanism of this fever and allied conditions, which was published in the *British Medical Journal* on July 28th, 1928 (p. 145). These authors admitted the difficulty, in many "quinine attacks," of excluding some other cause, such as exertion or chill; and Lieut.-Colonel S. P. James, in the July issue of the Kenya periodical, mentions that such measures as the provision in a district of adequate medical care and nursing, with attention to road making, housing, water supply, and the general welfare, bring about a significant reduction in this and others of the graver sequels of malaria. Colonel James advocates caution as regards the administration of quinine in this disease, and is sceptical about its prophylactic value in preventing infection—a different matter from the prevention of clinical attacks. Dr. O. R. Arnell, however, considers that the existing evidence for incriminating quinine is far from convincing, and he has contributed to the June issue of the Kenya journal a statistical note on what he terms the hypothesis that this drug is likely to cause, or to precipitate, an attack of blackwater fever. His main point is that conclusions based on the analysis of blackwater fever cases alone are likely to be entirely false, and he suggests eight groups of cases which should be investigated simultaneously, if a reasonably accurate deduction is to follow. These groups comprise malarial and non-malarial patients to whom quinine was or was not given, and who did or did not develop blackwater fever. Dr. Arnell recognizes the difficulty of differentiating those who have had quinine in sufficient quantity to be a real factor in such a comparison. He comes to the conclusion that, since this drug is completely excreted within twenty-four hours, and since haemolysis, if it is going to develop, will become manifest in three or four hours, it is reasonable to classify a person as being "quinine-free" if he has taken no quinine for thirty-six hours. The number of patients investigated on the lines suggested by Dr. Arnell is admittedly too small at present for any dogmatic conclusion. He believes, however, that in malarial patients blackwater fever is likely to develop seven and a half times more frequently if quinine is withheld than if it is given. Further, in non-malarial patients he concludes that there is no probability of blackwater fever developing, whether this drug is given or withheld. The evidence, though inadequate, seems to suggest the possibility that an attack of blackwater fever occurs in spite of, rather than because of, quinine administration.

THE PRE-SCHOOL CHILD.

The age at which compulsory education begins in England and Wales is five years. In Scotland and in most European countries it is somewhat later. Some education authorities, however, admit children below this age to their elementary schools, and the provision of special nursery schools for such children by local education authorities was made permissive by the Education Act of 1918. These nursery schools, established primarily for the sake of the children, are to be distinguished from day nurseries, established mainly for the sake of the mothers. In spite of a good deal of encouragement, at the end of the year 1927 only twenty-seven nursery schools were in existence, and only twelve of these had been established by local education authorities, the rest being under the auspices of voluntary bodies. The infant up to one year of age, or even two years, has, of course, of late years been the object of much public solicitude and action; concern for the child of from two to five years of age has been less pronounced. This era of comparative neglect now seems to be passing, and much more attention is likely to be given to the needs of these children in the near future. The nursemaid or even nursery governess of the ordinary type is being replaced by the highly educated and specially trained attendant and teacher. It may be said that everyone who has charge of a small child is conducting a gigantic experiment, the outcome of which is of profound importance; and except in homes where economic circumstances and cultural influences permit of the best conditions for its conduct and control, it is evident that such an experiment may most suitably be carried through at, or in connexion with, a place where the equipment and workers are carefully chosen rather than under the haphazard conditions and uninstructed observation of the majority of homes. The world of the baby and of the toddler is now recognized to be widely different from that of the adult, and the neurological conditions and psychological processes of the small child are being studied and understood as they have never been hitherto. It is coming to be acknowledged, too, that these conditions and processes may be the subjects of a truly scientific control, and that if this control is not brought to bear in the very earliest years an opportunity is lost which no amount of schooling at a later age can really replace or compensate for. Fortunately just now the experts in this field are beginning to expound and teach their subject in books which contain more than popular truism and commonplace, and which are really adequate to interest and instruct the intelligent parent and the teacher. One such book recently published by Messrs. Partridge in their "Home and School Library" can be strongly recommended. It is entitled *The Psychology of the Pre-school Child*, and is by Dr. James Drever and Miss Margaret Drummond.[1] It is therefore authoritative and trustworthy. In the first three chapters Dr. Drever gives an admirable account of the fundamental psychological principles involved in the study of the pre-school period, and Miss Margaret Drummond, in the remaining seven chapters, illustrates from her wide practical experience the way in which these principles find expression in the different stages of development of the young child, as it passes from what has been termed the period of omnipotence, through the period of magic, to the stage at which it slowly and imperfectly recognizes causal law (if this expression may still be permitted). The importance in this connexion of Pavlov's work on conditioned reflexes is recognized, but perhaps, when future editions are called for, it may be possible to apply this work more fully and positively and to include some practical indications not merely how to avoid the impressions and connexions leading to undesirable habits, but how to promote that growth of fresh physiological paths in the higher centres of the brain which will be most useful and advantageous when the child at five or six years of age passes on to the infant school or kindergarten.

A CONFERENCE ON MENTAL HEALTH.

The National Council for Mental Hygiene and the Tavistock Square Clinic have combined in organizing a conference on mental health, which will be held at the Central Hall, Westminster, from October 30th to November 2nd. Co-operating in this conference are a large number of organizations, including the British Medical Association, concerned directly or indirectly with the promotion of the mental health of the community, and, as announced in last week's issue (p. 701), it is hoped in the course of certain group

[1] *The Psychology of the Pre-school Child*. By James Drever, M.A., B.Sc., D.Phil., and Margaret Drummond, M.A. London: S. W. Partridge and Co., Ltd. 1929. (6s. net.)

discussions to correlate the personal experiences of magistrates, probation officers, teachers, and parents, responsible for the care and supervision of children whose mental life presents problems of special difficulty. At the inaugural meeting, under the chairmanship of Viscount Brentford, Sir Maurice Craig will speak upon the work of the National Council for Mental Hygiene, and make special reference to the necessity for early and preventive treatment of mental disorder. We understand that he will also make an appeal for funds to enable the work of the National Council and of the Tavistock Square Clinic to continue, and, as the need arises, to increase their scope. Other speakers on this occasion will be Dr. Letitia Fairfield, who will give an account of the child guidance movement, Sir Frederick Willis, and Dr. F. E. Fremantle, M.P. At the first session on October 1st Dr. H. Crichton Miller, Miss G. Coster, and Mrs. Neville-Rolfe will introduce a general discussion on sex education. At the second session a discussion on the personal equation in industry will be initiated by Dr. Millais Culpin and Professor Winifred Cullis. An exacting programme has been arranged for the three sessions on November 1st; at the first—presided over by Sir George Newman—Sir Humphry Rolleston, Dr. H. P. Newsholme, medical officer of health for Birmingham, Miss E. M. Lawrence, chief social worker to the Child Guidance Clinic, and Miss Viney of the College of Nursing will open a discussion on the place of mental hygiene in social and public health work; at the second session Dr. Cyril Norwood, headmaster of Harrow, will preside over a general debate, introduced by the Rev. L. W. Grensted and Dr. Helen Boyle, on the relation of the child and the parent; and at the third session, with Mr. Alexander Maxwell, chairman of the Prison Commission, presiding, Dr. J. A. Hadfield and Mr. Clarke Hall, magistrate at Old Street Police Court, will examine delinquency as a problem in mental hygiene. The following morning, Dr. R. H. Crowley, senior medical officer to the Board of Education, will preside over a group discussion, introduced by Miss E. M. Neville and Dr. E. A. Hamilton-Pearson, on the "problem child" at home and in school.

THE AUTUMN DINNER OF THE ASSOCIATION.

The Great Hall of the British Medical Association's House in Tavistock Square was transformed into a banqueting chamber on Tuesday evening, when the Council held its eighth annual dinner. The dinner was made the occasion of the first public inspection of the recent extensions to the House and of the reconstructed Library and Council Chamber. The guests were received by the Chairman of Council in the handsome room at the head of the staircase in the front of the new building, and from there they walked the length of the now much-extended wings to the Great Hall at the rear. Nearly two hundred and fifty sat down to dinner in the hall. The guests included the Minister of Health (Mr. Arthur Greenwood, M.P.), several medical and other members of Parliament, representatives of public authorities (one of whom was the chairman of the London County Council) and of the civil service, and the presidents of medical and kindred institutions, headed by Sir John Rose Bradford for the Royal College of Physicians, and Lord Dawson of Penn for the Royal Society of Medicine. A wider interpretation than usual had been given to the phrase "kindred institutions," and the guests included the titular heads of the great professional bodies representing the Bar, architecture, and accountancy. A large number of ladies were present, including Mrs. Burgess, who accompanied the President, and Miss Maclean, sister of the Past-President. Sir Ewen Maclean, who is in Melbourne, sent, together with the Australian Branches, a greeting by wireless. In a delightfully humorous speech Dr. E. H. Snell proposed the usual toast of "The Common Health," to which the Minister responded. Mr. Greenwood, who received a cordial welcome on his first appearance at the table of the Association, caused some laughter by remarking that he hoped to be in office long enough to solve all the problems which he had found awaiting him in Whitehall. He described himself as the only layman in the company, and the typical "man in the street," but he emphasized the happiness of the relations existing between the medical profession and his department. A Ministry run without regard to the profession, he said, would be a Ministry deprived of its most useful contact with experience. Dr. Walter E. Elliot, M.P., Under Secretary for Scotland in the last Government, made a brilliant speech in reply to the same toast. After some chaff at the expense of the Minister, he acknowledged that the differences between parties were differences of method rather than of principle. He thought it a good thing that there should be changes, and that representatives of different sections of the community should try their hand at the business of government. To Mr. McAdam Eccles fell the duty of proposing the toast of "The Kindred Societies," and, numerous and varied as these were, he managed most skilfully to weave them all into a complimentary oration. There were two responses to the toast, one by Dr. Andrew Balfour, who was able to relate all the various bodies, including the Royal Society and the Royal Colleges, to the London School of Hygiene and Tropical Medicine, of which he is director; and the other by Lord Riddell, who amused the company with a new batch of anecdotes. Dr. Langdon-Down, in a few words, proposed the Chairman's health, and paid a tribute to Dr. Brackenbury's gifts as a counsellor in professional affairs. The proceedings closed with Dr. Brackenbury's reply, in which he mentioned the sorrow of all his colleagues at the recent passing of a well-loved and honoured figure from Association gatherings—Sir Jenner Verrall. A fuller account of the speeches will be given in our next issue.

GENERAL MEDICAL COUNCIL ELECTION.

In connexion with the forthcoming election of two direct representatives for England and Wales on the General Medical Council, we publish in the *Supplement* this week the joint address issued to the electorate by Dr. H. B. Brackenbury and Mr. N. Bishop Harman, the candidates chosen by the Representative Body for support by the British Medical Association. A letter in support of the candidature of Sir Norman Walker, who is seeking re-election as direct representative for Scotland, will also be found in the *Supplement*. Formal notices of the election of two representatives for England and Wales, one representative for Scotland, and one representative for Ireland, signed by the President of the General Medical Council as returning officer, appear in our advertisement pages. In each case nomination papers must be delivered to the appropriate registrar in London, Edinburgh, or Dublin, on or before November 7th.

The Bradshaw Lecture before the Royal College of Surgeons of England will be given by Mr. R. P. Rowlands, M.S., F.R.C.S., on Thursday, November 14th, at 5 p.m.; the subject will be "A review of the surgery of the gall-bladder and bile ducts."

in the history of the relations of this is the visit of a party of a hundred udents from the universities of Jugo-slavia. The party arrived in London on Thursday of this week, and leave for Paris on October 22nd. The Jugoslav Society of Great Britain, who are welcoming them, have arranged, with the help of the Fellowship of Medicine, visits to representative medical institutions in London, and have prepared a general programme, which includes visits to the British Museum and other places of interest, and an evening reception at Crosby Hall. The Lord Mayor and the Lady Mayoress are entertaining the party to tea at the Mansion House to-day (Saturday, October 19th).

Nova et Vetera.

JOHN DALTON, PHYSIOLOGIST.*

BY

E. M. BROCKBANK, M.D., F.R.C.P.,

PRESIDENT OF THE SECTION OF HISTORY OF MEDICINE, BRITISH MEDICAL ASSOCIATION.

[In his introductory remarks Dr. Brockbank explained that he had chosen the subject for two reasons: first, for its special nature; and secondly, for personal reasons—namely, that he had heard many stories from two of his late octogenarian aunts who had hearsay information about John Dalton from their own relatives who were kin to him. One of these relatives had kept house for Dalton in Manchester from 1830 to 1835. One of the aunts inherited some personal objects of interest which belonged to Dalton, and letters written by him, and amongst the letters were two, hitherto unpublished, which show that he was attracted to a medical career, and which give some information about the training and habits of London and provincial doctors of the eighteenth century and of how to succeed in such a life.]

It was whilst John Dalton was teaching at Kendal (1789–93) that his thoughts turned to other fields of knowledge and work. With the thoroughness with which he dealt with any subject he wrote to various relatives on the matter. He had one objection, he said, to his teaching, and that was that it did not bring him in enough emoluments to support a small family with the decency and reputation he could wish should it fall to his lot to have to do so; he doubted not that he could adapt himself to any business that might promise to be of advantage, but it seemed most natural to turn to such wherein literary or scientific knowledge was requisite, as his pursuits and acquisitions hitherto had been of that nature. Under such a head stood law and physic, and of the two he preferred the latter. The great objection was expense. He calculated that three winters' study at Edinburgh would exhaust his resources, although he expected his board for each six months to cost no more than £15. If he were unable after all to succeed as a physician he could return to teaching.

An uncle to whom he wrote considered that both the professions of law and physic were totally out of reach of a person in his circumstances. He thought that the humbler sphere of an apothecary or attorney might, with a little capital and great industry, be within his powers. Another relative advised that his talents were best adapted to, and "that he would not only shine but be really useful in, that noble labour of teaching youth. He was far from thinking that physic would be a misconstruction or misapplication of his talents, parts or genius, so he much desired that Dalton might be guided by best wisdom in all his pursuits."

Dalton's views on the subject are expressed in two most interesting letters to a cousin, which have not previously been published.

Kendal 9th of 4mo. 1790.

DEAR COUSIN,

Having for some Time past had an Inclination to quit my present Profession of Teacher & enter upon some other where there may be an Expectation of greater Emolument I thought it not imprudent to acquaint thee with it & request thy Advice on the Subject, & the rather as I could wish to enter upon the Study of Physic (a Science in which I presume thou art no inconsiderable adept) provided my Circumstances will admit of it.

If I should come to such Determination I apprehend an Acquaintance with the principal Part of the Materia Medica will be deemed necessary & likewise sufficient before the entrance at College; a previous Acquaintance with the technical terms of Anatomy, Chymistry and Medicine will doubtless be useful, together with a knowledge of Botany.

Should any Occasion call thee to this Place in the Course of a Week or two I should be glad to converse with thee on the Subject, otherwise to be informed by Letter, how far my Scheme appears to thee likely or practicable, with such other Remarks relative thereto as may occur.

My Love to Cousin Nancy & Family &

I remain thy affectionate Cousin

JOHN DALTON.

George Bewley
Whitehaven.

P.S.—Taking a Fancy a few weeks past to determine as near as might be the Quantity of Matter discharged from the body by insensible Perspiration, somewhat like Sanatorius' famous Experiments, though I am ignorant of his Manner of effecting it, as well as of his Result, I shall subjoin my Observations.

He then records daily the quantity of food taken, the quantity of the evacuations, both solid and liquid, and the volume of the perspiration.

This P.S. is probably the first account of his observations on physiological processes, with himself for subject, or, to quote a recent writer, "on being his own rabbit"; but in 1787–89 he was applying his barometric observations to experimenting on the power of vacuum, or immersion in water, to destroy or overpower vitality in snails, mites, and maggots.

The next letter to his cousin carries the matter further.

Kendal 25th of 4th mo. 1790.

DEAR COUSIN,

I may acknowledge the Receipt of thy obliging letter, & that a few Days before I received one from Cousin E. Robinson & another from Uncle T. Greenup (whose Advice relative to the Profession of Law I had requested) upon the same subject as thine. Cousin Elihu's Sentiments nearly coincide with thine, but those of my Uncle are somewhat different; he represents to me that the Profession of a Physician is entirely out of my reach, that an expensive Education at College, & then a Course of Travels through a great Part of Europe, & a Visit to the several Universities are quite requisite, previous to any Practice; after this a Carriage and suitable Equipage, a genteel Appearance, &c., must be supported, or I should be deemed a Disgrace to the Profession. His Ideas are, I think, calculated for the Meridian of London. I consider a Visit to the foreign Universities, &c., though it may contribute towards his Accomplishments as a Gentleman, & perhaps towards his success & Reputation as a Physician, are of less Service to a Person's real knowledge of the Profession than the same Time spent in Practice would be. My Uncle moreover seems to think that if I could be content to move in the humbler Sphere of an Apothecary I might perhaps get a Livelihood from the Business.

I cannot say that I have yet fully determined respecting myself, but I hope I shall steer a due Course between a sudden and inconsiderate Conclusion and a dilatory Irresolution that loses the proper season for Action; & in the Mean Time shall spend my leisure Hours in such pursuits as are preparative to the Practice of Physic, whatever the ultimate event may be:—Respecting Botany I would observe that as few of our English Herbs are efficacious Articles in the Materia Medica, the Being able to distinguish & class them properly does not seem to me of so much Service, as an Investigation of their Organisation and Oeconomy, from which a skilful Person may be able to make judicious Inferences after a proper Comparison with the Structure & Oeconomy of Animals. With regard to Chymistry, I sometime since perused Boerhave's Treatise which I suppose is a capital one; making Allowance for the Time since it was written; also the Chymical (?) Essays of the present Bishop of Llandaff which are a good Introduction: I have likewise read Boyles chemical Tracts, but his Style is so tedious & verbose that one cannot reap the full Advantage from them, except they were condensed & digested a little better. With regard to Books on Anatomy, the Materia Medica, the Nature, Cause & Cure of Diseases, I have seen few or none, & should be glad if thou would inform me at some opportunity which of the great Number of Publications are most worthy of Perusal in thy Judgement. I mean of those thou hast seen thyself or heard recommended by others.

I am thy obliged Cousin,

JOHN DALTON.

George Bewley
Whitehaven.

* Extracts from an address given to the History of Medicine Section at the Annual Meeting of the British Medical Association, Manchester, 1929.

A great wish to become a doctor not being gratified, he accepted an offer to come to Manchester in 1792, at the age of 27, as teacher in mathematics and natural philosophy at the Manchester Academy, also called the New College. He soon joined the Literary and Philosophical Society of Manchester, to which during his life he communicated the following physiological papers:—

October 31st, 1794. Extraordinary Facts relating to the Vision of Colours with Observations.

April 7th, 1798. Essay on the Mind—Its Ideas and Affections; with an Application of Principles to Explain the Economy of Language. (Not printed.)

March 7th, 1806. On Respiration and the Causes of Animal Heat.

January 8th, 1830. Physiological Investigations arising from the Mechanical Effects of Atmospherical Pressure on the Animal Frame.

March 5th, 1830. On the Quantity of Food taken by a Person *in Health, compared with the Quantity of the Different Secretions* during the same period, with Chemical Remarks on the several Articles.

He recorded many original observations carried out on himself and deduced conclusions new to the physiology of his day, some of which still hold true.

[The full address has been printed for private circulation, and Dr. Brockbank will be glad to let anyone especially interested *in the subject have a copy.*]

RECURRENT DISLOCATION OF THE SHOULDER.

A REPORT BY DR. TAVERNIER OF LYONS.

ONE of the two subjects chosen for discussion at the annual meeting in Paris of the French Orthopaedic Society on October 11th was recurrent dislocation of the shoulder. Dr. LOUIS TAVERNIER of Lyons opened the session with a detailed report, summarizing the available information as regards its etiology and the various operative measures which have been employed for the relief of the disability. Although the condition is mentioned by Hippocrates, it was not till modern times that any accurate description, such as that of Dupuytren, was given. Its pathological anatomy has long been obscure, for it does not cause death, and therefore there are scarcely any museum specimens which illustrate it. Moreover, the evidence obtained at operations is conflicting. Each surgeon who has devised a procedure for its cure is apt to find at the time of operation the lesion which his method was devised to remedy. Turner Thomas, who has performed so many operations of capsulorrhaphy, is convinced that the capsule is in fault, being too lax. Mr. Blundell Bankart expressed the opinion *in a letter in the British Medical Journal* (1925, vol. ii, p. 978) that no competent surgeon who has exposed the joint at operation could fail to observe that detachment of the capsule and/or the glenoid ligament is the cause. All surgeons who have operated in divers ways record cures, but one of the difficulties in coming to a decision in this matter is the interpretation of this word "cure." When is it safe to say that the tendency to luxation from comparatively slight force no longer exists? Dr. Tavernier mentions many cases in which, after so long an interval after operation as two years, the luxation has recurred, yet such cases may easily and excusably have been recorded as cured.

Generally the lesions suspected of being causal have been confined to the soft parts, but of late the subject has been further complicated by the assertion of Grégoire and Bazy that certain deformities of the head of the humerus to which they have called attention may predispose to luxation and favour recurrence, or, together with injury, be the real causes of both.

Etiology.

In considering the etiology of this lesion one of the outstanding facts that are encountered is the great liability to it manifested by epileptics and athletes, 90 per cent. of the cases being found between the ages of 10 and 30 years. As regards sex, it is a striking fact that the proportion of recurrent dislocations among females is twice as great as the proportion of primary luxations, which, as Tavernier points out, suggests that there is some factor besides injury to be reckoned with, although the main cause may be trauma. Generally speaking, the subjects of this disability have well-developed muscles. It is astonishing, first, that there should be no trace of atrophy in these cases, and secondly, that such powerful muscles should not be able, by their tonic contraction, to keep the head of the humerus in its place, despite lesions of the capsule. The original accident in which dislocation first occurred has generally been a serious one, but it must not be forgotten that in some few cases slight efforts, such as throwing a stone, putting on a coat, fencing, or chopping wood, have produced the primary dislocation. In such cases surely there must have been a predisposing abnormality which favoured both the primary and the recurrent dislocation. Whether this abnormality consists in a deformity of the humeral head or of inadequacy of the glenoid cavity is still the subject of debate. What is the role of the kind and duration of treatment of the original dislocation in the production of recurrences? Here Tavernier finds a racial difference of opinion. The Anglo-Saxon orthopaedists—in which category he includes North Americans as well as the British—are unanimous in attributing it to too early abduction movements. The Germans did hold similar opinions, but after characteristically patient research they have arrived at the conclusion that, seeing that in a large proportion of cases immediate mobilization has not been followed by recurrence, while cases after prolonged immobilization still recur, they admit the inefficiency of the latter method. Tavernier thinks the capsular theories of the Americans, notably that of Turner Thomas, are too simple to answer to the complicated facts.

Symptoms and Diagnosis.

There is generally nothing about the first dislocation to indicate that it will recur, unless the slight violence which caused it or the fact of epilepsy give rise to apprehension. One point of diagnostic importance stands out in the account of symptoms, and that is the increasingly spontaneous character of successive recurrences. Indeed, recurrences after adequate trauma should not be included in our category, which would be better called "habitual" than "recurrent." Snapping shoulder (*épaule à ressort*) is excluded from this discussion.

Pathological Anatomy.

Unfortunately, the various lesions that have been described are not constant, so that it would seem that recurrence is not always due to the same cause, and that different anatomical conditions might lead to it. Post-mortem morbid anatomy offers practically no help. Moynihan's pathology of the living is but little more helpful owing to the generally restricted area of the field of operation. Radiography only gives information about the skeleton, but in a certain number of cases has shown malformations of the head and neck of the bone which are of importance. A certain number of observers have by this means recorded departures from the norm which are included in the general term of "hatchet-shaped head." Such changes are only evident when the humerus is fully rotated outwards. Some surgeons have laid stress on the importance of detachment of insertions of muscles into the humerus, especially the supra- and infra-spinatus; that of the subscapularis has been less often noted, and its importance is doubtful, seeing that division of this tendon has entered into some successful operations. Perthes, Clairmont, and Ehrlich attribute recurrence to detachment of the insertion of the external rotators, and the first in the course of eleven operations had to refix the tuberosity in six cases. But recent researches have diminished the im-

portance of these lesions, which have been only exceptionally demonstrated by radiography. Turner Thomas, in his large series of cases, reports no lesion of the peri-articular muscles. Moreover, Auvret, in his Paris thesis of 1907–8, shows reason to think that luxation complicated by fracture is likely to lead to limitation of movement and less liability to recurrence. On a review of the evidence Tavernier considers that these fractures are of little importance in this connexion.

Laxity of the capsule of the joint is the lesion most often noted by operators. Joessel in one case injected it with mercury, and found its capacity to be three times as great as normal. Only four operators are recorded to have found the capsule so tight that it was impossible to pleat it as was intended. The normal capsule, however, is loose, otherwise the free normal movements of the humerus could not be carried out. Operators in general give no precise details of the amount of dilatation, which is, indeed, not easily estimated. Turner Thomas, it is true, approaching the joint from the axilla, has found a thin-walled hernial protrusion of the capsule in which the luxated head rested. Tavernier makes little of this in view of the importance of rupture of the capsule, which is commonly found on its antero-inferior aspect close to its insertion into the glenoid ligament, or extending into this ligament itself. This split in the capsule leads into a sort of pocket beneath the subscapularis and in front of the neck of the scapula. This tear in the capsule he considers to be, if not the first cause of habitual dislocation, at least a necessary condition of it.

It is only after opening the joint and examining the capsule from the inside that the breach can be seen, and, even so, it is sometimes apt to be overlooked. The capsule, instead of splitting, may tear away the glenoid cartilage and periosteum from the neck of the scapula, thus allowing the head to be displaced in front of the denuded bone. This lesion, however, Tavernier considers to be exceptional. Enlargement of the bursa of the subscapularis and the presence of foreign bodies in the joint are only mentioned to be dismissed.

Lesions of the humeral head to which allusion has been made are more important. They are of two kinds: (1) a groove (*encoche*) corresponding to the line of junction of the head and neck and tuberosity, on the posterior aspect, and (2) various alterations in the form of the head itself. The hollow is described as being formed as though one had removed bone in the shape of a quarter of an orange. It is supposed that this hollow or groove catches on the edge of the glenoid cavity, and the two parts, acting like cog-wheels, cause the humerus to roll out of the joint. But however plausible this theory may be, it appears that the groove is not present in every case of habitual luxation. Alibert in 110 cases in the literature, taken at random, found its presence recorded in only thirty-five, but it is possible that it may have escaped notice in a number of cases. Some of the various deformities of the humeral head which have been grouped under (2) as "*hatchet head*" are represented in the figures illustrating the report. Alibert has found this abnormality present not only in all his own cases, but in twenty out of fifty-seven radiographical records in the literature, including cases of Turner Thomas, Eden, and, above all, Schultze. These various deformities all tend to make the humerus take up more room in its rotating movements, thereby to distend the capsule, and finally to tear it and escape from the cavity of the joint. The causes of such deformities of the head are quite obscure.

Pathogeny.

All that has been already said leads up to the theory that bony malformations prepare the way by distending the capsule; traumatism produces the first dislocation, and defective cicatrization of capsular lesions is kept up by the malformation of the head. The necessity of trauma for the production of the first dislocation explains the frequency of the lesion in the male sex, the athlete, and the epileptic. General laxity of the capsule, or laxity of its lower part only, has been cited as the cause. Turner Thomas, from an experience of more than 150 cases, considers that luxation is the result of exaggerated abduction, permitted by such laxity which itself is the result of allowing too free movement soon after the primary luxation. But the many failures of capsulorrhaphy prove the inadequacy of this explanation. Perthes, Quénu (and Tavernier himself formerly) attributed habitual luxation to a torn capsule; Broca and Hartmann to detachment of the capsule and periosteum; Popke, Kraske, Hildebrandt, and others to tearing of the edge of the glenoid ligament or the cartilage itself or the bony edge of the cavity; all of these are apt to happen in ordinary luxations, and it is necessary to explain why they do not heal in cases of habitual dislocation, as they usually do after violent dislocation.

Tavernier now turns from all these alleged causes to malformations of the humeral head, and possibly in some cases insufficient size of the glenoid cavity, as the real predisposing causes of habitual dislocation.

Treatment.

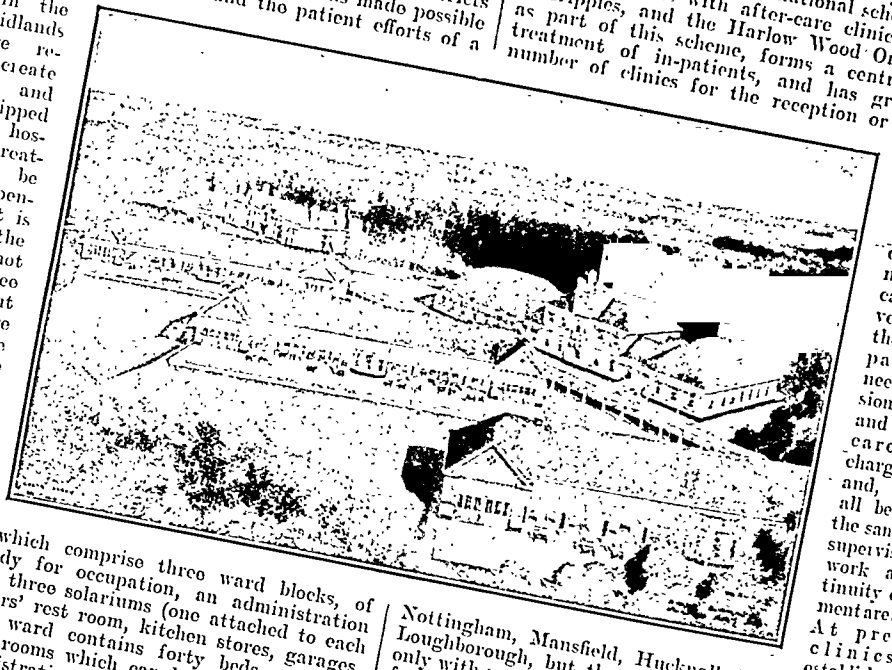
The following curative operations, based on the supposed pathology of the condition, have been performed, and are described and illustrated by the author. (1) Capsulorrhaphy with or without incision or resection of capsule, shortening of tendons, and reinforcement of the capsule with fascial graft. (2) Suture of the split in the capsule. (3) Reinsertion of the detached tendon of the subscapularis. (4) Section or autoplasty of muscles to combat supposed lack of muscular equilibrium. (5) Enlargement of the glenoid cavity. (6) Resection of the head of the humerus. The following palliative operations have been undertaken: (1) Arthrodesis of the shoulder-joint. (2) Operations designed to limit abduction. (3) Tendon-suspensions. (4) The interposition of a bony obstacle to luxation. Except the generally unjustifiably severe operations of arthrodesis and resection and the operation of interposition of an osseous obstacle, all these operative procedures are discussed and dismissed as insufficient, for all have been followed in a number of cases, sooner or later, by recurrence, unless they permanently limit movement.

Tavernier holds that all attempts at cure depending on muscular or fibrous support are bound to fail sooner or later owing to yielding of the restraining band or its attachments. Osseous obstacles he considers as much more likely to be permanent. Of these he refers to that of Eden, who implanted a bone-graft from the tibia on the bared anterior surface of the neck of the scapula overhanging the joint, so as to prevent anterior dislocation. Kellogg Speed of Chicago, with the same aim in view, drives a bone peg taken from the tibia into the antero-inferior border of the glenoid cavity, leaving it projecting far enough to check luxation. He and Phemister have recorded good results. Nevertheless, the operation of Oudard is preferred to these. It consists in lengthening the coracoid process by dividing it across and interposing between the cut surfaces a graft from the tibia four centimetres long. In more recent operations, instead of introducing a graft, Oudard has split the coracoid process obliquely and lengthened it by sliding down one half with the insertions of the coraco-brachialis and biceps attached. In the original and in the modified operation he also shortens the tendon of the subscapularis. In this operation the author considers, however, that the osseous block is everything, and that the effect of the operation on the tendon is negligible. The results, he says, are excellent. No relapses are recorded, even after seven years, and the functional results are also good, but it is admitted that in some there is reduction of the range of abduction and in a few some pain. The original grafting operation no doubt provides the longest and most solid coracoid process, but Oudard has had some trouble with sinuses and necrosis of the graft; the modification by splitting and sliding does not expose the patient to the risk of these complications, and appears to be equally effective.

For our part we cannot but think that this operation, which, as Tavernier says, is almost unknown outside France, must be followed by some limitation of extension and abduction. He has collected a series of thirty-one publications relating to the subject, and this bibliography is appended to his report.

HARLOW WOOD ORTHOPAEDIC HOSPITAL.

AN interesting ceremony took place on August 3rd, when Their Royal Highnesses the Duke and Duchess of York opened the Harlow Wood Orthopaedic Hospital, near Mansfield, Nottinghamshire. This hospital is situated on an admirable site in one of the fringes of Sherwood Forest, and will be able to serve not only a large agricultural area, but some of the most populous districts in the East Midlands. Its establishment was made possible by the generous contributions and the patient efforts of a large number of persons in the East Midlands who were resolved to create a modern and fully equipped orthopaedic hospital where treatment could be given on open-air lines. It is true that the hospital has not been opened free from debt, but what debt there is will soon be cleared if the present stream of contributions is maintained.



The inset photograph gives a general idea of the arrangement of the buildings, which comprise three ward blocks, of which two are ready for occupation, an administration block, nurses' home, three solariums (one attached to each ward block), a visitors' rest room, kitchen stores, garages, and a lodge. Each ward contains forty beds, and has attached at one end rooms which can be used for paying patients. The administration block is linked up with all three wards by a covered way, and contains at one end the operating theatre, x-ray department, and treatment rooms, at the other the kitchens, and between the two the offices of the secretary and the clerical staff. Each bedroom in the nurses' home is supplied with running water. The responsibility for the building operations was assumed by the Sir Jesse Boot Property and Investment Trust, which generously undertook to carry out this task without making any profit. The architects were Messrs. Bromley Cartwright and Waumsley of Nottingham. The site itself was presented by the Duke of Portland, and he and the Duchess of Portland, who has been elected president of the hospital, took a prominent part in the opening ceremony.

The hospital owes its origin largely to the success with which, during the great war, the military orthopaedic hospitals, or special military surgical hospitals as they were then called, were able to treat many of the wounded and train them for civilian life. Shortly after the war Sir Robert Jones evolved the national scheme of central orthopaedic hospitals with after-care clinics for the treatment of cripples, and the Harlow Wood Orthopaedic Hospital, as part of this scheme, forms a central hospital for the treatment of in-patients, and has grouped round it a number of clinics for the reception or after-care of out-patients. At the out-patient clinics, each of which is managed by its own independent committee, are carried out preventive work, the treatment of patients not needing admission to hospital, and the after-care of discharged patients, and, the clinics all being under the same surgical supervision, team work and continuity of treatment are assured. At present, clinics are established at Nottingham, Mansfield, Hucknall, Worksop, Newark, and Loughborough, but the hospital, it is hoped, will deal not only with patients coming from these clinics, but with those from other areas also; irrespective of county boundaries, it is ready to co-operate with any practitioner who feels that it is near enough to be of service to his patients. The Harlow Wood Orthopaedic Hospital should thus form an important centre for treating the more advanced cases of deformity, and afford a means for co-ordinating all work for cripples in the East Midlands. It may be hoped that its efforts will contribute to a solution of the serious problem of turning cripples into self-supporting citizens.

On the consulting staff are Sir Robert Jones, Mr. Naughton Dunn, and Mr. R. G. Hogarth as honorary consulting surgeons; Dr. J. Wilkie Scott as consulting physician; Mr. J. Llewellyn Davis as consulting surgeon; and Mr. S. A. S. Malkin as surgeon in charge. The resident surgical officer is Mr. John Campbell.

BRITISH EMPIRE CANCER CAMPAIGN.

AT the quarterly meeting of the Grand Council of the British Empire Cancer Campaign, held on October 14th, with Sir JOHN BLAND-SUTTON, Bt., in the chair, the grant was renewed to the Cancer Hospital for the special scheme of radiological research which is being carried out on the effects of x rays upon the blood constituents and bone marrow, with the object of correlating the findings of experimental work with those observed in the treatment of patients suffering from cancer. A further grant of £250 for one year was also made to Mr. E. Nevill Willmer for the continuation of his research work on the relation of the growth of cultures to the chemical nature of the media in which they grow.

A report from the Finance Committee by Sir Richard Garton showed that grants made by the Campaign during the last year for research purposes amounted to £25,000, while donations received during that period only amounted to £17,000. The Finance Committee asked that special efforts should be made during the ensuing year to increase the donations to the Campaign in order that it may be able to subsidize the work of the cancer research centres at their maximum activity.

The general secretary reported that details of the policy which the National Radium Commission proposed to adopt, relative to the co-ordination of existing bodies interested in the use of radium, had not been so far communicated to this Campaign. The Grand Council expressed a hope that early steps would be taken to bring about co-ordination between the work of the Radium Commission, the use of the radium in the hands of King Edward's Hospital Fund, and the various radium centres in existence which have been formed by the British Empire Cancer Campaign.

It was reported that the North of England Council of the Campaign, combining the counties of Northumberland, Durham, Cumberland, and Westmorland, had been successfully founded under the presidentship of the Duke of Northumberland, with Sir Thomas Oliver as chairman of the Executive Committee. The inaugural meeting of the Council is being held this week at Newcastle-on-Tyne. The Grand Council was informed that it is intended that a substantial part of the funds resulting from this appeal shall be devoted to the establishment of a radium institute in the North of England.

New Zealand.

[FROM OUR CORRESPONDENT IN WELLINGTON.]

The Cancer Campaign.

As a result of the visit to New Zealand of Mr. Sampson Handley a branch of the British Empire Cancer Campaign has been formed in New Zealand, with headquarters at Wellington. The Governor-General is patron, and the Prime Minister and Minister of Health are keen supporters of the movement. A thoroughly trained research worker is being appointed from England to institute cancer research at the New Zealand Medical School in Dunedin, where proper facilities are available. From his experience he will understand the best lines to follow here in the Empire-wide attack on the cancer problem. Divisions of the branch are being formed in the larger centres of population, and an attempt is being made to enlist the sympathy and co-operation of the public. In addition to the work in the main centre of research at Dunedin there is urgent need for accurate statistical research in connexion with the hospitals in the cities and larger towns with a view to uniformity. To this end, delegates from New Zealand to the Australasian Medical Congress in Sydney will obtain valuable data, such as the method employed in organizing the cancer records of the Prince Alfred Hospital. In each of the main hospitals in New Zealand a cancer committee has been formed, composed of a surgeon, a physician, a pathologist, a radiographer, and a radiotherapist, to review each case, or suspected case, and confer as regards diagnosis and treatment. This course of action will lead to a certain amount of segregation of cancer patients and to their close supervision. Radium treatment has hitherto been too much in the hands of the radiotherapists, and not sufficiently under surgical control. As the scheme progresses it is hoped that surgeons will become more qualified in the uses of radium, and better instructed in its limitations. The New Zealand Branch of the British Medical Association has been prominent in organizing the proposed campaign. In this part of the world cancer appears to be as common as in Great Britain.

Sir Ewen Maclean's Visit.

Sir Ewen Maclean, past-president of the British Medical Association, arrived at Wellington on August 26th, and left the following evening on his way to the Australasian Medical Congress in Sydney. His time during his short visit was fully occupied. He spoke very helpfully on the international problem of maternal mortality, and was interested in investigating the low infant mortality rate in New Zealand. Sir Ewen was entertained to dinner by the medical profession of Wellington, and a free and frank discussion took place on possible means whereby visiting members from Dominion Branches could come into closer and more helpful contact with the parent body in London. This discussion opened up the question of the need for more efficient organization of post-graduate instruction in London, at present so much inferior to the arrangements at the clinics and medical schools of the United States. It was pointed out that a New Zealander could travel to America in sixteen days, whereas the journey to England usually occupied about six weeks. The visitor to America had no difficulty in seeing anything he wanted, but in Great Britain, unless he presumed on the kindness and hospitality of a friend on a hospital staff, he found few facilities for post-graduate work. Even if he was prominent in the British Medical Association overseas, unless his visit to the homeland synchronized with the Annual Meeting, the colonial visitor could seldom make effective contact with headquarters. If post-graduate work were organized in London and the other centres on business lines visitors would be only too pleased to pay reasonable fees rather than submit to annoying and haphazard ways. The clinics of the United States were quite alive to the post-graduate needs of the profession in Australia and New Zealand, and desired pan-Pacific co-operation. Although science had no frontiers it was reasonable to expect more cordiality and help from kith and kin than from strangers. Sir Ewen Maclean showed that he has a clear view of the whole situation, and his visit to the "camp fires of the Southern Legions," to borrow Mr. Victor Bonney's phrase, should be productive of much good. Sir Ewen is reported to have said: "In so far as medical relations are concerned, I will use my best endeavour to set up the most useful and intimate connexion between the medical profession in New Zealand and in London and the other big centres, particularly in regard to post-graduate teaching. I believe the time is ripe to develop such a scheme."

Scotland.

Glasgow Mental Colony.

LENNOX CASTLE, Stirlingshire, together with surrounding grounds, was purchased some time ago by the Glasgow District Board of Control for conversion into a colony for the care and treatment of mental defectives, and was formally opened for this purpose on October 5th by the Right Hon. William Adamson, Secretary of State for Scotland. Mr. Adamson remarked that the opening of this institution indicated that Scotland was awakening to the duty of providing for the less fortunate section of the community. When the Mental Deficiency and Lunacy Act of 1913 came into operation, the Glasgow Board of Control had been faced with the responsibility of providing accommodation for mental defectives. The institution of Stoneyetts had been converted for this purpose, and had been managed with conspicuous success. Later, in 1916, Barnhill had been licensed as an institution for housing fifty-two mental defectives, and in 1922 Blinkbonny, Falkirk, had been licensed for eighty patients. These institutions were, however, only palliatives, and in 1927 the Glasgow Board of Control had purchased the estate of Lennox Castle, with the ultimate intention of erecting a village colony which would accommodate 1,000 mental defectives. Meantime, the mansion house, which would ultimately be used as a nurses' home, was being utilized for the accommodation of 150 female defectives. After May 15th, 1930, the supervision of lunatics and mental defectives would be taken over by the new local authorities, in this case the town council of Glasgow. The speaker expressed the hope that this institution would provide, in full measure, the service for which it was being built.

Scottish Insurance Committees' Conference.

A two-day conference of the Scottish Association of Insurance Committees was held at Ayr at the end of last month; several points affecting insurance practice in Scotland were discussed. It was decided to make representations to the Government for the provision to all insured persons of specialist and consultant treatment as essential parts of a complete and satisfactory medical service. Reference was made to the hiatus which at present existed in the scheme of health services between the statutory age of leaving school and the statutory age for entering national insurance. Large sums were spent on child welfare during the first five years of life, with most beneficial results, and during school years the health services were continuously available at considerable cost, but with equally satisfactory results. Yet between the ages of 14 and 16 years there was no provision for health services, and this was a serious anomaly. It was reported by Mr. A. B. Gilmour, of the Central Checking Bureau, Glasgow, that during 1928 the number of prescription forms handled on behalf of fifty-four insurance committees in Scotland was 2,655,737, which was a decrease of 93,000 compared with 1927. The value of these prescriptions (exclusive of the cost of insulin) was £147,328, a decrease of £4,410 compared with 1928, while the difference in cost between the years 1924 and 1928 was nearly £14,000. It was pointed out that the tariff price for 100 units of insulin had been reduced by successive stages from £1 6s. 8d. to 2s. 7d. After some discussion, a motion was passed that the cost of drugs, including insulin, supplied to insured persons under treatment in voluntary institutions, should be a charge against the Drug Fund of the Insurance Committee, instead of having to be paid from the funds of the voluntary institutions.

Quarrier's Orphan Homes.

A unique Scottish institution, the Orphan Homes at Bridge of Weir, celebrated the centenary of the birth of the founder, William Quarrier, on September 27th. The institution comprises a sanatorium, an epileptic colony, and a farm, in addition to the homes. Lord Maclay presided at the thanksgiving ceremony, and pointed out that over 20,000 boys and girls had been cared for, educated, and trained within the homes, and to-day in almost every part of the world there were to be found men and women, playing useful parts, who had cause to bless that institution and pay tribute of remembrance to William Quarrier and his wife. It was a remarkable fact that no less than £2,000,000 had been gifted since 1871 without the issue of a single public appeal. Three daughters of the founder were present at the celebrations, which were attended by 3,000 visitors.

England and Wales.

Medical Charity in Yorkshire.

The twenty-first annual meeting of the Medical Benevolent Society for the East and North Ridings of Yorkshire (including the city of York) was held last week at the Hull Royal Infirmary, with the president, Dr. D. M. Mackay, in the chair. The annual reports of the honorary treasurer and the honorary secretary were received and adopted. From these it appeared that the financial position remained satisfactory, only one case (that of the widow of a former member) needing help during the past year. The cash balance is over £160, in addition to nearly £3,000 invested capital, which has been steadily accumulating during the twenty-one years of the society's existence, and from which a reliable income accrues. The election of officers resulted in Dr. D. M. Mackay of Hull being reappointed president; also, as vice-presidents, Dr. E. M. Hainsworth of Hull, and Dr. H. J. Mackenzie of York, who are respectively honorary treasurer and honorary secretary. All members of the medical profession living in the area described in the above-mentioned title of the society are eligible for membership: application for particulars should be made to Dr. Mackenzie, 254 Bishopsthorpe Road, York.

St. Marylebone Children's Rheumatism Supervisory Centre.

In 1926 a supervisory centre with reference to rheumatism in children—the first of its kind in England—was instituted at the St. Marylebone General Dispensary. The director of the centre, Dr. Halls Dally, has now published a report of the work of the centre since its beginning, together with an analysis of the first 100 patients who attended, the results being grouped under three main headings — namely, environmental, clinical, and biochemical. In view of the small number of cases the conclusions reached are only submitted as tentative, but it is hoped that they will be considered sufficiently encouraging to warrant further investigation along the same lines, with a view to determining how the rheumatic child differs from other children. It was found that, generally speaking, there was an increase of the velocity of sedimentation of the red blood corpuscles, even when focal infections appeared to be absent. Cardiac involvement was present in all the children who manifested a lowered alkaline reserve, and the urinary examination in these cases revealed a deviation in the direction of increased acidity. Cases which showed a deviation to the alkaline side were eventually classified as not being rheumatic on clinical as well as on biochemical grounds. The total sulphate excretion was disproportionately high in sixty cases, and the phosphate excretion was relatively diminished in forty; as many as seventy cases showed an abnormal carbon-nitrogen ratio. An excessive faecal loss of calcium was found in forty cases. Evidence was therefore obtained pointing to a definite tissue retention of acid, and it is proposed to carry this investigation further with a view to establishing a correlation between a certain type of "rheumatic" children and the acid retention type of adult "rheumatic" patients. Although the blood uric acid content was within the normal limits in all cases, the urinary ratio of uric acid to urea was below normal in over sixty, the latter ratio being probably an accurate and sensitive index of acid retention in the tissues. Dr. Halls Dally adds that an attempt is being made to associate the clinical and biochemical findings in order that an interpretation may be defined of each individual in terms of endocrine function, with special reference to the thyroid, pituitary, and suprarenal glands.

Central Midwives Board.

At a meeting of the Central Midwives Board for England and Wales, held on October 4th, a letter was read from the registrar of the Nurses' Registration Board, Tasmania, asking that reciprocal arrangements with regard to the registration of midwives might be entered into between the Central Midwives Board and the Government of Tasmania. The board agreed to offer reciprocity on terms similar to those already accorded to the midwifery authorities of the various States in Australia. It was also decided to accede to a request made by Dr. Farquhar Murray and Dr. Ranken Lyle that pupil midwives training at the Princess Mary Maternity Home, Newcastle, might, as part of their training, attend cases of doctors in private practice. As a condition of its consent the board stipulated that only pupil midwives who had completed twenty cases and entered in their last month of training should be allowed to engage in such service, and that the work should be conducted under the general supervision of the training midwife of the hospital. In response to a suggestion that pupils in training under the Somerset County Association might obtain part of their intern experience at the Mary Stanley Training Home at Bridgwater, the board decided that cases in this home might form part of the pupil's training experience only after she had completed five intern cases at some other institution.

Correspondence.

TONSILS AND ADENOIDS IN HOSPITAL PRACTICE.

Sir,—With reference to the correspondence on this subject, and Dr. R. R. Simpson's suggestion that the Section of Diseases of Children should press the matter further and advise giving up the practice of operating upon out-patients, as President of the Section of Diseases of Children I have thought over this matter carefully since the Manchester Meeting, and I feel that the time is not yet ripe to press for abolition of this practice, provided that certain measures are taken for after-care.

These measures have been taken by the Manchester Children's Hospital for some time, and my colleague Mr. Arnold Jones outlines the essentials of the scheme in his letter which follows. He also gives an account of the inquiry which he is making to ascertain whether children do suffer severely from being operated upon at out-patient departments when they are sent to their homes afterwards in an ambulance.

To give up the practice of operation upon out-patients means the provision of extra beds. We cannot decrease the already overtaxed accommodation for other surgical cases, so that the provision of these beds means expensive building. My feeling, therefore, is that we should wait for definite evidence before we ask hospital boards to incur additional expense: if the inquiry shows that the children do suffer, then we should press home the need for provision of beds and abolition of the practice wholeheartedly.—I am, etc.,

Manchester, Oct. 14th. C. Paget Lapage.

Sir,—Before embarking upon a crusade to substitute in-patient operations for out-patient operations for tonsils and adenoids, with the vast expense which this would incur (almost certainly diverting money which should be expended upon more urgent problems), we should be quite sure that the issue is a vital one. To my mind this has not been shown.

My opinion, based upon an extensive experience of these operations during the past twenty-five years, is that if

due and proper precautions are taken out-patient operations for tonsils and adenoids can be performed with as good results and with as few complications as those which follow in-patient operations. This is my strong impression, but, wishing to gain knowledge from recorded facts, last August I instituted an inquiry into the subject at the Royal Manchester Children's Hospital. This inquiry I propose to continue for a year.

I, or the senior medical officer, see all the patients operated upon both in hospital and as out-patients, a fortnight after operation. The history of that fortnight is inquired into and noted. If a patient fails to appear the inquiry is pursued through the post. Thus at the end of a year it will be possible to compare the results of in- and out-patient operations from definitely recorded facts.

The due and proper precautions referred to, which have been in force at the Royal Manchester Children's Hospital for some years, are:

1. The cases are selected: (*a*) none come from a distance greater than five miles; (*b*) no child with a "chest" or "heart" is operated on as an out-patient; (*c*) the older children are operated on as in-patients.
2. The patients lie on couches in the recovery rooms for three or four hours, are attended to by a nurse, are examined before leaving by the medical officer, and are then sent home in the hospital ambulance.
3. If there is any doubt about the patients' condition the medical officer detains them in hospital.
4. When the weather is inclement no out-patient operations are done. This mainly applies to east winds, fog, and extreme cold.

In addition, I have recently made arrangements for the inspection of homes where there may be doubt as to their suitability, and I intend, if practicable, to have all the patients visited at their homes by a nurse the day after operation.

I submit that, if similar inquiries were set on foot by other surgeons at various hospitals, in a year's time a valuable mass of real evidence could be obtained. Until that is done it seems to me that any action taken by the profession in this matter, as suggested by some of your correspondents, would be premature and based on insufficient evidence.—I am, etc.,

Manchester, Oct. 15th. J. ARNOLD JONES.

RADIUM IN SURGERY.

SIR,—In his letter in the *Journal* of October 12th, criticizing certain paragraphs in my book on *Radium and its Surgical Applications*, Mr. Forsdike raises a question of considerable interest, the answer to which is by no means so simple as his letter suggests. The experiments of Bédère and Laborde indicate that with a screen of platinum 0.6 mm. in thickness there is for all practical purposes a total absorption of the primary beta rays. The surface layers of the screen give off, however, a secondary radiation of soft beta rays, produced by the impact of the gamma rays, and very destructive in their action on living cells. It would seem, therefore, that any increase of the thickness of the platinum screen beyond 0.6 mm. is futile, and that it is to the abolition of this secondary radiation that attention must be turned.

A far more effective method, in my opinion, is to use sources of radiation so small that secondary rays are negligible, and, where an intense effect is desired, to bury these in the substance of the tumour where local destruction of tissue is actually an advantage. I am now using exclusively seeds containing 1.5 or 2 millicuries of radon, screened by only 0.3 mm. of silver, and of the immediate results in carcinoma of the oesophagus and of the breast I can speak with some confidence from a very fair experience. In no case have I noted any ill effects such as might be due to inadequate screening, whilst the minute dimensions of the seeds reduce to a minimum the trauma associated with their introduction.

The whole question is, however, one on which it is impossible to dogmatize, and the present divergence of opinion upon so elementary a point shows how important for progress is the careful control and observation of our cases, for it is only upon our results, and not upon any theoretical considerations, that we must ultimately depend.—I am, etc.,

London, W., Oct. 15th. H. S. SOUTTAR.

THE CONTROL OF MEASLES.

SIR,—Your leading article on measles (October 12th, p. 675) is extremely timely, but, quite naturally, in the space available for such an article, the whole of the points concerned cannot be adequately discussed.

You deal very definitely with *immediate* mortality, but the appalling effect of measles is not merely felt at the time of the epidemic, but results in a very considerable amount of morbidity causing early mortality. The results of a calculation of the ultimate mortality attributable to an epidemic of measles would give us a shock. I recall an epidemic in the early years of this century affecting fifty-five children. The immediate mortality was twenty-seven. At the end of twelve months an attempt was made to trace the remaining twenty-eight, with the amazing result that one live child only could be found. This was, of course, exceptional, but those of us who deal with numbers of sick children for many years find our measles patients coming back and dying of other conditions, which can be directly attributed to their attack of measles.

It is obvious, therefore, that any attempt to deal with this problem is of vital importance, in the strictest sense of the term. Production of serum from cases of measles or from convalescents will prove of very great advantage if an epidemic takes place in a delicate community—for example, in an infants' ward in a children's hospital—but until some satisfactory prophylactic of animal origin is obtainable the method cannot be widespread. Incidentally, I may say we have come to the conclusion that the administration of a moderate amount of serum is the plan to adopt, permitting the child to have a mild attack of measles free from complications.

But because the animal supply is not yet available there is no necessity for us to stand idle. The mortality and morbidity of measles can be reduced enormously with our present knowledge. You refer in the last paragraph of your leader to the influence of vitamin A. I would suggest that you might have been more dogmatic, and have stated that the mortality and morbidity of measles are the measure of the incidence of rickets. Unfortunately, even in these days, the newly qualified practitioner is firmly convinced that rickets is indicated by bony deformities, and is therefore a disease of the second year of life. The textbooks and, I regret to say, the teachers do not emphasize sufficiently that rickets—not mild rickets—is a general disease, laying the mucous membranes open to the attacks of pathogenic organisms. Hence children who do not receive adequate quantities of vitamins A and D when attacked by measles have a very low resistance to mucous membrane complications, and immediately up jumps the incidence of broncho-pneumonia, enteritis, and otorrhoea.

Obviously, then, the end of the matter is nutritional, and our efforts should be concentrated on the adequate provision of satisfactory fats. To come down to practical details, I would suggest (*a*) doubling the milk consumption, (*b*) the provision of cheap edible fat having satisfactory quantities of the necessary vitamins. Butter is, of course, our mainstay in this respect, but the vitamin content of butter is extremely variable during the whole of the year, and very low during the winter months, just at the very time when it is most essential, and as eggs are at that time scarce, and correspondingly expensive, our difficulty is intensified. I would therefore suggest the provision of a margarine with adequate quantities of added vitamins.

At the present time the doubling of the milk supply is impossible, and, having regard to its appalling character, probably undesirable. There is no difficulty in providing an adequate supply of the necessary vitamins with an edible fat, and I am satisfied that such provision would bring our mortality and morbidity rates of measles down to an astonishingly low level—and, surely the British Medical Association can find no better object than the reduction of this enormous preventable national loss.—I am, etc.,

JNO. D'EWART.

Booth Hall Infirmary, Manchester, Oct. 14th.

"THE IDEAL MEDICAL MUSEUM."

Sir,—I read with interest the short article on "The ideal medical museum" which appeared in the *British Medical Journal* for October 12th (p. 679). While I yield to no one in my admiration of the excellent work which Dr. Daukes has carried out in connexion with what is now the Wellcome Museum of Medical Science, it seems desirable, if only in the interests of accuracy, to point out that the article in question is calculated to convey a wrong impression with respect to the genesis of that museum and the development of the so-called "graphic" system of display.

When I was appointed director of the Wellcome Bureau of Scientific Research in 1913 I pressed strongly for the establishment of a teaching museum arranged on somewhat special lines, for I had long felt that existing medical museums were in certain respects unsatisfactory. Mr. (now Dr.) H. S. Wellcome was good enough to give his consent, but, owing to the fact that I had to proceed abroad, I was unable to make a beginning with a museum of tropical diseases until 1914, a fact duly chronicled in Dr. Daukes's interesting and useful book.

The museum was started on graphic lines, of which I had already obtained some experience owing to my participation, on behalf of the Sudan Government, in the great Hygiene Museum at Dresden in 1911, and later at the Ghent Exhibition, where I had charge of the display of several diseases, including leprosy. The Ghent exhibits, indeed, served as a nucleus for the Wellcome Museum at 10, Henrietta Street, Cavendish Square, and there was then and there evolved a scheme of graphic representation on screens and on the walls, which later formed the subject of a joint illustrated paper by Dr. Daukes and myself, which appeared in the *Journal of Tropical Medicine and Hygiene* for September 1st, 1920. This paper explains how and why the museum came into being.

The museum developed slowly but steadily on these lines, and though its growth was hindered by the war there was soon after the close of hostilities a fairly complete representation in colour and black-and-white of nearly all the important tropical diseases. It had, indeed, attained such dimensions that a curator was required, and Dr. George Buchanan, now on the staff of the South African Institute for Medical Research at Johannesburg, was appointed. He rendered most useful service, and his skill as an artist was most helpful. Indeed, examples of his illustrative ability are still to be seen in the museum at Gordon Street (Endsleigh Gardens). I would also like to pay a tribute to the admirable work of the first artist to the museum, Mr. Schwarz-Lenoir, who, until the time he was unfortunately laid aside by illness, laboured most assiduously and successfully at depicting tropical disease in all its aspects.

Dr. Buchanan remained curator until 1919, when Dr. Daukes was, as stated in your article, appointed. No better selection could have been made. Not only did Dr. Daukes share the ideas which I had endeavoured to bring into being, but his experience at Leeds had given him fresh conceptions, while he had also what can only be called a "flair" for museum work of this kind. He was of the greatest assistance and, after my connexion with the Wellcome Bureau terminated, he was appointed director of the museum, and given full scope for the exercise of his talents, with the result which is now visible, and on which your article comments, and with justice, so favourably. At the same time the scheme adopted for the museum of the Wellcome Bureau did not originate with Dr. Daukes, but in the manner I have indicated.

I may add that, with the help of Sir Wilfred Beveridge and Dr. Newham, the museum of the London School of Hygiene and Tropical Medicine is being developed along similar lines, and that we encourage our students to make use of both museums, regarding them as complementary one to the other, and recognizing that the Wellcome Museum, so far as medicine is concerned, covers a wider field and possesses resources to which we cannot aspire.—I am, etc.,

London School of Hygiene and Tropical Medicine, Oct. 14th. ANDREW BALFOUR.

P.S.—After this letter had been written it came to my knowledge that my old colleague Dr. Daukes had also drafted a communication which he proposed sending to your *Journal*. As the views expressed in the two letters were similar, Dr. Daukes decided to withhold his note, especially as mine entered somewhat more fully into detail. —A. B.

TREATMENT OF INFECTIONS WITH S.U.P. 36.

Sir,—Having introduced S.U.P. 36 and used the drug experimentally and clinically since 1923, I was much interested to read Dr. R. M. Pearce's paper in the *British Medical Journal* of October 12th. The uses and the action of this drug and other symmetrical urea compounds are described in *The Nature of Disease*, Part II; but allow me to repeat them in brief.

S.U.P. 36 should be injected in any acute inflammatory condition as early as possible two days in succession, and again on the fifth day, if necessary, in 0.005 to 0.01 gram doses. The dose is not of paramount importance, although I use generally 0.01 gram in all cases, including babies, children, and animals smaller than man. In animals larger than man I use up to 0.1 gram doses. S.U.P. 36 is invaluable in the milder infections caused by the staphylococcus, pneumococcus, *Micrococcus catarrhalis*, the micro-organisms of influenza, etc. It is equally useful in acute infections in animals, such as distemper in dogs, the coughing of horses, the various forms of garget, udder infections, etc.

This drug is useful in some of the toxaemias of pregnancy, in post-operative acidosis, in venous thrombosis, and in certain cases of hay fever and asthma. It will prevent insulin from causing intoxication, it will check the shock occasioned by histamine, and act as an antidote in intoxications caused by the non-metallic elements, such as the halogens, oxygen, sulphur, etc. S.U.P. 36 would appear to act as a conductor through the two negatively charged hydroxyl groups in the 8-positions of the naphthalene rings. Infections and non-metallic negatively charged intoxicants rob the host's main resistance—the protein particles in the plasma—of electricity, and this is made good by the conduction of electricity from the positively charged hydrogen atoms in the hydroxyl groups. These hydrogen atoms function as metallic atoms like the arsenic atoms in arsenobenzene. Indeed, there is no fundamental difference in action between S.U.P. 36 in influenza and salvarsan in syphilis. Both act by increasing the patient's resistance, not by directly killing the invading micro-organisms.—I am, etc.,

London, W., Oct. 12th. J. E. R. McDONAGH.

Sir,—I was much interested in the article in your issue of October 12th (p. 663) by Dr. Raymond Pearce on the use of S.U.P. 36 (para-benzoyl-para-amino-benzoyl-amino-naphthol 3:6 sodium sulphonate). As the result of a knowledge of the work of Mr. J. E. R. McDonagh—and it is to his fertile brain we owe this as well as other drugs—I have made some use of S.U.P. 36 in acute inflammations of the middle ear, as also in acute rhinitis and other acute inflammations of the upper respiratory passages.

Observations of cause and effect are in such matters peculiarly liable to fallacy, but my impressions of the effects of the drug are fairly similar to those found by Dr. Pearce in influenza. I am sure the period of the common cold is shortened. I note that Dr. Pearce says: "The injections were usually made into the gluteus medius muscle, and only very trivial complaints of pain were ever received. Occasionally the injections were made into the deltoid muscles, where in one or two cases rather more pain was suffered," and the object of this letter is to suggest to him that he might try the abdominal fat as a suitable site for injection of this drug. From self-experiment the injection is much less unpleasant there than when made into a muscle. An injection into the abdominal fat did not with myself, for instance, interfere with my using a golf club at all, whereas an injection into the gluteus, and still more into the deltoid, made me prefer not to play golf for a few days. I have seen no ill effect from the injection into the abdominal fat.—I am, etc.,

York, Oct. 12th. PETER MACDONALD.

SIR,—Dr. Pearce's article on the use of S.U.P. 36 is of particular interest to me, because I used this substance on more than fifty consecutive cases of influenza, with results differing widely from those which he obtained.

The patients were treated on the first or second day of the illness with an intramuscular injection of 1 c.cm. of the preparation in question. The dose was repeated daily for three days. Comparing these cases with a like number treated on the usual lines, no beneficial effect, as evidenced by reduction of the duration of fever, pains, length of time in bed, or convalescence, could be established.—I am, etc.,

London, W.1, Oct. 14th. A. H. DOUTHWAITE.

MILK A CAUSE OF ARTERIO-SCLEROSIS?

SIR,—Some years ago a communication of mine, on milk and arterio-sclerosis, was considered worthy of space in the *British Medical Journal*, December 6th, 1924 (p. 1082). This encourages me to submit a further note on the same subject. The paper on diseases of the coronary arteries, by Dr. G. A. Allan, published in your issue of August 11th, 1928 (p. 232), in which he states,

"in almost all cases prognosis is bad, particularly in view of the absence of any evidence that arterio-sclerosis, atheroma, or calcification *can be influenced materially by any known line of treatment*,"

still further encourages me in this request. If milk is in fact a cause of arterio-sclerosis, then so long as milk, and cheese, are allowed to patients suffering from this disorder all treatment is likely to be in vain.

I believe I have suffered severely from arterio-sclerosis, but am now very much better, though my age is several years more than threescore and ten. Before describing my own experience, however, I would first draw your readers' attention to Sir Clifford Allbutt's work on this disease, published in April, 1925. After reading it more than once, very carefully, I am driven to the conclusion that the profession has no idea as to the cause of the disease. His book, however, leads me to think it is closely allied to the condition generally known as high blood pressure. It is with more confidence, therefore, that I ask my colleagues to consider my suggestion, especially as milk is believed by some leading consultants to have a pronounced stimulating effect upon the heart.

Secondly, I feel our thanks are due to Dr. Rutherford Daw for his paper on the incidence of arterio-sclerosis, published in the *Journal* of July 25th, 1925 (p. 162). It points to a close connexion between arterio-sclerosis and calcium degeneration. While all can readily understand Nature taking calcium from one tissue where it is needed in health to another to repair damage caused by disease, we cannot readily conceive that this transfer produces disease. Where we find calcium producing disease we are justified in concluding it does so because it is present in excess of bodily needs. We *must, then*, look to our food for the most likely source of this excess. Do we find this in milk? In my opinion, yes. Primrose McConnell states that one gallon of milk, containing 14 per cent. of solids, has 1.23 oz. of ash. The ash of cow's milk has 17.8 per cent. of lime, which amounts to 105 grains per gallon, or 6½ grains per glass. I would ask those hospital surgeons who have the opportunity of procuring healthy arteries to ascertain the amount of calcium in them; this information would add greatly to our knowledge, and be complemental to Dr. Dow's paper. In support of my contention, I must become personal; I hope, however, your readers will consider this justified. I will try and put my case impartially, as though I were an onlooker.

Until nearly 50 years of age I was a very heavy milk drinker. I like it; it agreed, I thought, with me, and it is an ideal food. During my boyhood at home we had an unstinted supply. As a medical student my lunch was a pint of milk, with a few biscuits, a bun, or sponge cake, to prevent large curds forming in the stomach. In after years, especially in hot weather, my midday meal was on similar lines. Early in my professional life I noticed my radial arteries were very visible and tortuous. I attached no importance to this: I thought they were somewhat abnormal.

Over twenty years ago the idea occurred to me that milk, owing to its large proportion of calcium, might have some effect in producing atheroma. Later, I began to think it would also have a tendency towards causing arterio-sclerosis. I thereupon practically abstained from the use of it. My radial arteries were then very prominent and tortuous. Noticing lately that they had ceased to be conspicuously prominent and tortuous, and altogether more normal, I asked Dr. W. J. Baird of Bury to examine them and tell me what he thought. I did this because he has kindly acted, from time to time, during the last twenty years, as my medical adviser, and while so doing he has remarked on the bad state *of my arteries in general. Incidentally, my friend Dr. Reginald* Clarke to a great extent corroborates Dr. Baird as to the state of my arteries. In February, 1922, during a casual visit, he tested my blood pressure, and made the following note: "I noticed there was a general thickening of the arteries, the radials visible, somewhat hard, and rolled under the fingers when palpated; blood pressure 208 left, 210 right."

Dr. Baird now reports as follows: "About twenty years ago I had occasion to examine Dr. James Holmes, and found his radial arteries very hard; his temporal arteries were also very hard and tortuous. I called his attention to it, and advised *caution in exercise, etc. I examined him again recently*, and found a very great improvement. The radials were only slightly hardened, and the temporals were not tortuous or hard as formerly. He told me about his experience with and without milk diet, and I must say the improvement is astonishing, and the cessation of milk as a food significant."

The bearing of this on treatment is obvious. Assuming that milk is a causal factor in arterio-sclerosis, I suggest the absolute, or nearly absolute, abstention from milk and its products, excepting cream and butter, which are only the fatty portion of milk.—I am, etc.,

Bury, Lancs, Oct. 10th. JAMES HOLMES, M.D.

DIAGNOSIS OF ANAEMIAS BY DIFFRACTION.

SIR,—I have been indicted by Dr. A. Pijper in his letter published on October 5th (p. 649) on three counts, of which the first two are that I did not give him credit for his pioneer work in the diagnosis of anaemias by diffraction methods, and that I did not refer to his recent paper. In my paper published on July 13th (p. 48) I did credit him with his main discovery in these words.

"A thin blood smear acts as a very efficient diffraction grating and splits up the rays from a small source of light into a brightly coloured halo like a circular rainbow (Pijper)."

I also gave him full credit in my two earlier papers in the *Lancet* and *Clinical Journal*. But this third paper of mine in the *British Medical Journal* of July 13th was very condensed. The Editor—from lack of space—had to strike out eight of my ten illustrative cases, and also deleted the following passage, which I gladly quote.

"Dr. A. Pijper has now described (*British Medical Journal*, April 6th, p. 635) his improved method, with what is, in effect, a large camera with a simple uncorrected lens. A central partition enables him to compare abnormal with normal blood, and he points out that the distance between the violet and red bands is a measure of the anisocytosis. The method demands alignment with a Pointolite or arc lamp, and seems a device rather for the laboratory than for the clinician. Judging from my experience when I used my camera method I should have great difficulty in judging the exact margins of the red, yellow, and violet bands, specially of the colourless haloes of many cases of pernicious anaemia. Whereas in the halometer the sharp red edge of the halo yields one definite reading instead of three vague ones."

Doubtless this passage, *had it been printed*, would have more than satisfied Dr. Pijper's second indictment. Incidentally I may add that Dr. Pijper has already committed the fault against which he now declaims. For, after I had shown that a camera answered the purpose of his dark room, he adopts a camera-like apparatus and does not acknowledge the fact or mention my camera paper which I had sent him.

His third indictment is that my halometer is not original, but is a distorted version of his method. Certainly, I found that lenses he used were not necessary; as regards originality, old Thomas Young of Emmanuel College, Cambridge, discovered all the facts about it a century before. We are all indebted to Dr. Pijper for applying the method of Young to blood smears and thus measuring the average diameters of red cells rapidly instead of by the

very lengthy method of Price-Jones. The latter made the invaluable discovery that enlarged red cells are the most reliable and characteristic feature of pernicious anaemia. Since liver apparently always cures in the earlier stages of this disease (and its special degeneration) the early diagnosis of pernicious anaemia has suddenly become of the utmost importance.

All I claim for the halometer is that it renders available to the clinician all this esoteric knowledge at a moderate price in a simple form, which will pack into his bag, enabling him to diagnose for himself (or eliminate) pernicious anaemia in its earliest stages instantly and reliably from a thin blood smear. This was not possible before. When Dr. Pijper has seen and tested the halometer he now abuses, I think he will find that it modestly and accurately performs these services—now really indispensable.—I am, etc.,

Hull, Oct. 12th. FRANK C. EVE, M.D., F.R.C.P.

THE ROYAL COMMISSION ON THE ALCOHOL QUESTION.

SIR,—I write to draw the attention of your readers to the constitution of this Commission, which has been appointed under the Home Office: (1) to inquire into the working of the licensing laws; (2) to inquire into "the social and economic aspects of the question"; (3) "to examine and report upon proposals for amending the law in England and Wales." The personnel, as published on September 26th, consists of a lay chairman, seventeen lay men, and three lay women. The *Times* remarks, "Contrary to some expectations, no member of the medical profession has been appointed"; while the *Observer* states, "As the drink problem touches public health at many points, it will be foolish and weak if one medical man and one medical woman are not placed on this Commission." It appears to me that the omission to appoint any scientists is one that, viewed from the following two aspects alone, should not be overlooked by medical bodies.

Trade interests are heavily represented on the Commission, and in any recommendations will doubtless seek to show how the commercial value of England may be increased by this or the other policy; but there is something else at stake, that is man's destiny—the production of progressively perfected men and women. Therefore, firstly, is it to the nation's credit that scientists should be excluded from a body appointed to advise the nation on a question involving an issue of this magnitude?

Secondly, as to the "social aspect," here again we might ask whether, from the point of view of the individual, financial or commercial interests and those to which the medical profession is pledged are always identical. May not the health of the individual be a more important factor in bettering social conditions than the production in, or influx into, the country of greater and greater wealth? However camouflaged the wording of the terms of reference be with regard to it, discussion must hark back to the highly technical question of drug addiction in the individual; and to exclude technicians from any part in formulating advice to the nation under this head would seem to be absurd.—I am, etc.,

Braunton, N. Devon, Oct. 9th. C. A. MORTLOCK-BROWN.

THE HEART IN MODERN PRACTICE.

SIR,—The review of my book *The Heart in Modern Practice*, which appeared in your esteemed *Journal* for June 29th, contains the words "neither failure nor venous congestion appears in the index." On the contrary, the index contains the item "Heart failure, 20, 33, 78, 189, 354," and the subheading "*Relation* to infection, 93." Aside from this, the review is informing and correct. It is my desire, in case a subsequent edition is published, to be given freedom to expand the portions of the text that may be improved thereby.—I am, etc.,

Boston, Mass., Oct 2nd WILLIAM D. REID.

Obituary.

DR. JABEZ DAVENPORT WINDLE, medical officer of health for Southall, Middlesex, who died on October 5th, at the age of 64, received his medical education at Owens College, Manchester, and University College, London. He obtained the diplomas L.R.C.P.I. and L.M.Ed. in 1857, the L.R.C.S. in 1859, and the M.R.C.S.Eng. in 1891. He graduated M.B., Ch.B.Vict. in 1898, and proceeded M.D. in the following year. He was for many years a member of the British Medical Association, and was honorary secretary of the Section of Pharmacology when the Association met in Aberdeen in 1914. A colleague writes: Dr. Windle always seemed to me the ideal scientific general practitioner who combined intense devotion to the science of clinical medicine with the ability to inspire absolute confidence in all his patients. During forty years of exceptionally busy general practice he was at the same time doing original work in the investigation of problems of cardiac irregularity, and published papers on the subject in the *British Medical Journal*. He had a panel practice of 3,000, which he treated single-handed, in addition to a private practice of equal proportion, which included 250 midwifery cases a year. He was also medical officer of health and medical officer of the isolation hospital for a population of 30,000. There were also other appointments which he held, yet he was never without his polygraph, and continued to collect beautiful tracings at all times and seasons. He took up polygraph work at its very beginning, soon after Mackenzie invented it, and accumulated a splendid collection of beautifully selected tracings of all varieties of rare cardiac abnormalities, especially of pulsus alternans. When faced with one of those interesting but baffling problems of diagnosis which arise from time to time, when some hedging, evasive answer might be given by most practitioners to the anxious relatives, he would, to my astonishment, tell them with the utmost frankness that he did not know what was the matter; they were quite satisfied that if he did not know then neither could anybody else. By his very large practice and frugal mode of living he certainly amassed a large fortune during his long years of practice. There were very many people whom he treated for a decade without receiving one payment to any of the bills sent; they could very well have afforded to pay, but he never put them into court or ceased attendance. His whole interest lay in the daily problems of his clinical work, and he was restless if away from it for more than a few days.

Deep regret is felt among a wide circle of friends at the death, on July 7th, in Wellington, New Zealand, of DR. PATRICK MACKIN, who was born at Dunavil, co. Down, Ireland, in 1864, and went to New Zealand in 1882. He began his medical education at Otago University College and the Dunedin Hospital. In 1888 he became a medical student in Glasgow, and gained experience in some of the large hospitals in Scotland and in England. After obtaining in 1891 the diplomas L.R.C.P., L.R.C.S.Ed., L.R.F.P.S. Glas., and L.S.A.Lond., he sailed for New Zealand and started practice in Wellington. In 1894 he returned to Great Britain for further study, graduating M.D.Brussels and obtaining the F.R.C.S.Ed. in the following year; he then went back to Wellington, and became one of the leading practitioners in that city. Travel was one of his chief hobbies; another was the keen desire to keep himself abreast with the latest discoveries in medical science and treatment by periodical trips for refresher courses in Europe. In addition to his professional attainments Dr. Mackin was held in the highest esteem for his many fine qualities of head and heart. He diffused cheerfulness wherever he went, and his natural kindness found active expression in many acts of compassion and generosity. He was a sympathetic and skilled physician, cautious in judgement, and highly esteemed as a clinician of the conservative and safe type. His loss is felt as a personal one by the many patients, rich and poor, who knew and loved him, and much sympathy is extended to his widow.

Among those who attended the funeral of Sir Jenner Verrall on October 7th the name of Dr. E. Rowland Fothergill should have been included.

The Services.

MEMORIAL TO SIR WILLIAM BABTIE.

IN the chapel of the Queen Alexandra Military Hospital at Millbank, on October 9th, a marble tablet was unveiled and dedicated as a memorial to Lieut.-General Sir William Babtie, V.C., K.C.B., who died in 1920. A brief memorial service was conducted by the Chaplain-General to the Forces, the Rev. Dr. A. C. E. Jarvis, and afterwards the memorial was unveiled by Lieut.-General Sir Charles Burtchaell. In performing this ceremony Sir Charles Burtchaell said that William Babtie was an officer of great merit and high ability. He was beloved by all who knew him. His long service in the army was conspicuous for distinguished bravery on the battlefield and constant devotion to the advancement of every phase of the work of the Royal Army Medical Corps and the welfare of the British soldier. In these tasks he never faltered and never failed; as this tablet would for all time testify. The tablet was then dedicated by the Chaplain-General. It recorded the outstanding events of the late General's career in the army, extending over thirty-six years. He was Deputy Director-General of the Army Medical Services, 1910–14, Director of the Medical Services in India, 1914–15, and later Inspector of Medical Services at the War Office. Among those attending the ceremony were Lady Babtie and her daughter, Field-Marshal Sir George Milne (Chief of the Imperial General Staff), General Sir Walter Braithwaite (Adjutant-General to the Forces), Lieut.-General H. B. Fawcus (Director-General of the Army Medical Service), Lieut.-Generals Sir Arthur Sloggett and Sir Matthew Fell (former Directors-General), and Major-General Sir Alfred Blenkinsop. Sir William Babtie at the time of his death was a member of the Council of the British Medical Association and of its Naval and Military Committee.

Colonel H. E. M. Douglas, V.C., C.M.G., D.S.O., late Royal Army Medical Corps, has been selected for promotion to major-general and for the appointment of Deputy Director of Medical Services, Southern Command, India, vice Major-General J. M. Sloane, C.B., C.M.G., D.S.O., who is retiring at his own request.

Brevet Colonel J. S. Bostock, C.B.E., Royal Army Medical Corps, will succeed Colonel Douglas as commandant of the Royal Army Medical College, London.

Medico-Legal.

A SURGEON'S FEE.

IN its issue for July 5th, 1929, the *Surrey Mirror and County Post* reported a meeting of the Reigate Town Council, held on July 1st. The report included the following item, with reference to legal proceedings instituted by Dr. M. W. Baker and his partner, Dr. C. H. Laver of Redhill, for the recovery of professional charges in respect of an emergency operation performed by Dr. Laver five years previously in the corporation's Isolation Hospital at the request of the medical officer.

An Action Settled.

The Finance and General Purposes Committee reported that at their meeting, on June 17th, the town clerk presented a summons in the county court served upon him in connexion with an action brought by Messrs. Baker and Laver against the corporation for the recovery of £21 for performing a mastoid operation on a patient in the Isolation Hospital on May 23rd, 1924, the hearing of the case being fixed for Wednesday, June 26th. The committee recommended that the town clerk be instructed to take all necessary steps for defending the action.

Mr. Spranger proposed that the matter be considered by the council in committee. Mr. Townshend seconded, and this was agreed to. Alderman Malcomson said the case had been adjourned, so that it would come before them again.

The council considered the matter for some time in committee, and on again resuming in open council an amendment was carried to the effect that the town clerk be instructed to pay the amount and the county court costs which had been incurred.

It may be assumed that Drs. Baker and Laver did not begin legal proceedings until they were satisfied that a settlement of their claim could be obtained in no other way. The moral will not, we hope, be lost upon those members of the medical profession who find themselves in like circumstances.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following candidates have been approved at the examination indicated:

D.P.H. [illegible]
Je
Is
L. R. Sharma.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE.

A COURSE of forty-nine post-graduate lectures in biochemistry is being delivered on Thursdays and Fridays at 4 p.m. at University College, London; they began on October 17th. The syllabus for the first term includes lectures on the chemical study of the cell in relation to its environment, and the chemistry of the chief components of plant and animal cells. During the second term lectures will deal with the kinetics and dynamics of systems of biological importance, and also with plant synthesis. During the third term lectures will be given on metabolism, the chemical study of growth and reproduction, and physiological action in relation to chemical constitution. The course is free to students of University College who have paid a composition fee in the Faculties of Science and Medical Sciences; the charge to others is 9 guineas for the session, or £3 13s. 6d. for any one of the terms. Application for tickets should be addressed to Mr. C. O. G. Douie, University College, London, W.C.1.

UNIVERSITY OF GLASGOW.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—W. B. Adam, D. A. Agnew, D. M. Airlie, Ann T. Allan, J. G. Allardice, Margaret W. Anderson, Margaret C. Barron, N. Beaton, R. Bewick, G. G. Binnie, W. J. Blackley, C. A. Boland, M. C. Brogan, Isobel M. Brown, W. S. Burnet, G. F. A. Caldwell, D. A. Cameron, I. M. Christie, *R. Cochran, R. Cole, E. C. R. Couper, Eileen G. Craig, J. W. Crawford, R. S. Dewar, R. B. Douglas, J. † Distinction in midwifery.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council meeting of the Royal College of Surgeons was held on October 10th, when the President, Lord Moynihan, was in the chair.

The annual report of the Council, to be presented to the Fellows and Members at the annual meeting on Thursday, November 21st, was approved and adopted.

Mr. Hugh Lett was appointed a member of the Committee of Management of the Conjoint Examining Board in the vacancy occasioned by the retirement in rotation of Mr. G. E. Gask.

Primary Fellowship Examination.

A letter of August 10th last from Dr. T. C. Routley, general secretary of the Canadian Medical Association, was read, reporting that of the 37 candidates who had applied for admission to the Primary Examination in Anatomy and Physiology for the F.R.C.S.Eng., held at Toronto from August 6th to 10th, 23 ultimately paid their fees and sat for the examination. The following 9 candidates were approved:

J. H. Beasley, J. M. Bruner, G. A. Fleet, F. L. Horsfall, H. D. Isaacs, R. Marnham, H. J. Muth, L. R. Olver, V. N. Shirodkar.

It is proposed to hold another Primary Examination for the F.R.C.S. at Montreal next year.

Membership.

Diplomas of Membership were granted to the following 6 candidates, who had now complied with the by-laws:

C. S. Kah, D. Sheehan, P. D. B. Spence, F. R. Stansfield, E. H. Parkinson, T. J. Millin.

Licence in Dental Surgery.

On the recommendation of the Board of Examiners in Dental Surgery it was decided that, after July, 1930, candidates for the Licence in Dental Surgery be required to pass in Part II of the Pre-medical examination in Elementary Biology, as required of candidates for the L.R.C.P., M.R.C.S. It was also decided that, while not more than two terms' work in dental mechanics might be recognized before Part II of the pre-medical examination was passed, no instruction in anatomy and physiology should be

recognized before the pre-medical examination had been completed—that is, chemistry, physics, and biology.

The University of Cairo (dental department) was added to the list of recognized dental schools at which the curriculum for the Licence in Dental Surgery may be taken.

Gifts.

The President reported that he had received a cheque for £10,000 from the Public Trustee in respect of the legacy bequeathed to the College by Mrs. Eliza Macloghlin for scholarships for medical students, to be founded in memory of her husband, the late Mr. Edward P. P. Macloghlin, M.R.C.S. A committee was appointed to make such modifications in the original scheme for the administration of the trust drawn up in January, 1905, as may be necessary, and to take the necessary steps to put it into operation. The President reported also that Lord Melchett had offered £500 a year for seven years for a research scholarship at the Royal College of Surgeons. The President was requested to convey to Lord Melchett the Council's appreciation of his liberality and their grateful acceptance of his offer.

The Council accepted with thanks a copy of the Hon. John Collier's portrait of Charles Darwin, presented by Mr. Arthur Jaffé.

TESTIMONIAL TO SIR RONALD ROSS.

SIXTH LIST OF CONTRIBUTORS.

WE now print a further list of those whose donations, amounting to £820 16s. 5d., were received between August 11th and September 12th, in response to the appeal on behalf of the Ross Award Fund published in our issue of May 11th. The total amount in hand on September 12th was £9,768, including bank interest and upwards of £3,285 received from Singapore through the *Straits Times*, and £75 from the *Malayan Daily Express* Fund, Kuala Lumpur. The list published below does not include anonymous contributors or those whose initials only have been supplied. Donations should be sent to Lloyds Bank, Ltd., 110, High Street, Putney, S.W.15.

Dr. W. R. G. Atkins, W. I. Andress, D. C. Andrew, Admiral E. Astley-Rushton, S. Abbotts, Mr. and Mrs. A. N. Anderson, Amalgamated Tea Estates Co., Ltd., Anglo-America Direct Tea Trading Co., Ltd.; M. Adda, H. Andrew.

O T. Bryant, A. K. Barnes, J. W. Bisacre, British Indian Tea Co., Ltd., per Rev. H. J. Bashan, D. M. Birch, Mrs. T. E. Bayliff, Miss Baildon, Mr. and Mrs. J. P. Bulkeley, Lady Grace Barry, Mrs. E. Banning, Miss E. H. Bolton, E. B. Beazley, Earl Buxton, Miss Ada Bray, Judge Burgis, Dr. and Mrs. J. J. Bond, A. K. Boyd.

Consolidated Tea and Lands Co., Ltd., per Miss R. Cole, Miss C. E. Cowen, Mrs. C. H. Contes, Miss Clark, H. Cooper, B. Chambers, Mrs. Winifred Cole, Mr. and Mrs. C. F. Courtney, Miss E. Carpinter, Miss Cottam, Mrs. M. A. Clarke, Miss C. E. Clarke, Mrs. M. G. Coppinger, E. S. Currey, O. G. S. Croft, W. J. Crampton, Mrs. G. S Clarncross, Mrs. Chittenden

Mrs. C. A. Davies, Miss Duff, Mrs. Dewhurst, E. Da Costa.

E. J. Ereaut, Mrs. W. Edgeley, Miss L. M. Elliott, Miss D. Ellis, H. V. Edwards, Mrs. Emmer.

C. Frost, M. T. Foord, Mrs. M. W. Fergusson, Mrs. B. Franks, W. H. Fillingham, Miss M. Field, Mrs. Foster, Mrs. J. Fraser.

Mason, M. Macaskie, C. H. S. McArthur, Rev. W. H. Maude, Mrs. P. Munn, Miss K. Mitchell, Mrs. Malkin, Macfarlane and Hutchinson, C. Martin, C. M. Masterman, Miss D. Meyor.

P. C. Norman, Norfolk Square Nursing Association, Miss Olga Nethersole, Mrs. G. Neve, C. Neale

Mrs S. H. Oversley, Wilfrid Oats.

Mrs. M. Parry, B. L. Phipps, Mr. W. H. Perry, Mrs. T. Petre, D. and H. Penfold, Miss C. E. Pickard-Cambridge, E. Penrose, Mrs. Pittar, Mrs. Paulgrave.

Dr. W. H. Robertson, Lady C. Rhodes, Miss Robinson, E. R. Ranald, H. W. Raynor, Miss Lilian Russell, G. J. Rallings, Mrs May Ross, R. J. Reeth, J. Robbins, Mr. H. S. Reid, Miss Ramsay, M. Reilly, Mrs. A. M. Rutland.

Dr. J. G. Stevens, Miss J. Stephenson, H. F. Saunders, Mrs C. Starnes, Mrs. A. Smith, R. Barkeley Smith, B. Trevor Smith, M. Skeete, P. Simpson, Major E. M. Slaughter, Mrs. J. E. Shaw, Steel Bros. and Co., Ltd., Mrs N. Swanson, Rev. and Mrs. C. W. Sowby, C. M. Simiango, Lieut.-Colonel T. G. N. Stokes, A. H. Sharpes, Mrs. P Shrubb.

Jean Tyas, Mrs. E. M. Tucker, Mrs. and Miss Taylor, A. J. Tucker, Mr. and Mrs. Tumbridge, Colonel H. L. Templer, A. W. Targett, Mrs. C. Thomas, Mrs. Turnbull, Miss M. L. Taylor, The Misses E. and M. Turtle.

C. L. Vernon.

E. W. Willey, Leslie R. Walton, Mrs. Jane Watson, Mr. F. Williams, H. G. V. Walsh, Mr. and Mrs. James Wigan, W. H. White, Mrs. P. Warren, Mrs. R M. Wolseley, Mrs. Welsford, Mrs. E. E. Williams, Miss M. Wormule, Mrs. Watson, Miss Worth, L. J. Kemp Welch, C. F. Woodward, Mrs. E. B. Webster, A. E. Wynn, Miss L. Wales, Mrs. E. Wickham, Miss White, Mrs. Wyatt.

Sir Alfred Yarrow, Mr. R. W. Yule.

Medical News.

THE annual dinner of the Royal Society of Medicine will be held at the May Fair Hotel, Berkeley Square, W.1, on Thursday, November 21st, at 7.30 for 8 p.m. The Prime Minister, the Minister of Health, and the French Ambassador have consented to be the society's guests of honour.

THE annual dinner of the Chelsea Clinical Society will be held at the Hotel Rembrandt, Thurloe Place, S.W.7, on Tuesday, October 22nd, at 7.30 for 8 p.m. The programme of the forthcoming session includes the following subjects for debate: treatment of climacteric disorders in women; the the present position and possibilities of physical treatment; sweating; defaecation; micturition; coughing; sleep. These discussions will take place respectively on November 19th, December 17th, January 21st, February 18th, March 18th, April 15th, and May 20th, at the Hotel Rembrandt, and will each be preceded by an informal dinner at 7.30 p.m.

ON November 1st the People's League of Health will commence a series of lectures on "Racial and Individual Welfare," to be given on seven consecutive Fridays in the lecture room of the Medical Society of London, Chandos Street, Cavendish Square, W.1, at 6 p.m. The lecturers include Sir Thomas Oliver, Dr. A. F. Tredgold, and Mr. Harold Cox. Tickets can be obtained from the headquarters of the league, 12, Stratford Place, W.1.

AT the meeting of the Medico-Legal Society to be held at 11, Chandos Street, W.1, on Thursday, October 24th, at 8.30 p.m., Lord Riddell will deliver his presidential address on ancient laws and modern women. Members of the Medico-Legal Society are invited by the Hunterian Society to attend a discussion on the doctor and the motorist to be held in The Cutlers' Hall, Warwick Lane, E.C., on Monday, November 18th, at 9 p.m.

TWO Chadwick Lectures on "The Histological Basis of Health" will be given by Professor J. Boeke of Utrecht University at 5.15 p.m., in the British Medical Association House, Tavistock Square, W.C. The subject of the first, on Tuesday, October 29th, at which Sir William J. Collins will preside, is "The tissues in youth and age," and that of the second, on Friday, November 1st, with Sir James Crichton-Browne in the chair, is "The nervous system in relation to health." Another Chadwick Lecture, on Friday, November 22nd, at 8.15 p.m., at the House of the Royal Society of Arts, John Street, Adelphi, will be given by Professor A. E. Boycott on "The causes of cancer." Admission to these lectures is free, without ticket.

INCLUDED in the programme of the Child Study Society, London, are the following lectures, which will be delivered at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.1, on Thursdays, October 24th and 31st, and November 14th, at 6 p.m.: Co-education, by the Rev. Cecil Grant; the use of books in the school and home, by Mr. H. C. Dent; and the child and the cinema, by Lady Cowan.

THE Fellowship of Medicine announces that the following lectures will be given at the House of the Medical Society of London, 11, Chandos Street, Cavendish Square: on Monday, October 21st, at 5 p.m., Mr. H. W. Carson will speak on indigestion from the surgeon's standpoint; on Tuesday evening, October 22nd, at 8.30, Dr. L. S. T. Burrell will deal with intrathoracic tumours; and on Friday evening, October 25th, at 8.30, Dr. Burrell will lecture on bronchiectasis, abscess of the lung, and empyema. The last two lectures are part of a series suitable for M.R.C.P. candidates, and the fees are payable at the lecture room. A demonstration of cases in the wards will be given by Dr. Ernest Fletcher, at the Royal Chest Hospital, City Road, on Tuesday, October 22nd, at 2 o'clock; a surgical demonstration will be given by Mr. Herbert Paterson at the London Temperance Hospital, Hampstead Road, on Thursday, October 24th, at 2 p.m.; these demonstrations are free to medical practitioners. A special post-graduate course in medicine, surgery, and the special branches will be given at the Metropolitan Hospital, Kingsland Road, from October 21st to November 2nd; the course will occupy each day from 10.30 to 5.30, with special demonstrations and lectures, operations, and clinical work. Lunch will be provided at the hospital at a small charge. The subjects of courses to be held in November include: ante-natal work (four Fridays at 5 p.m.); medicine, surgery, and gynaecology (daily for three weeks); venereal disease (every afternoon for four weeks); neurology (daily at 5 p.m. for one month); proctology (all day for one week); and orthopaedics (all day for two weeks). Copies of all syllabuses and tickets of admission may be obtained from the secretary of the Fellowship, 1, Wimpole Street, W.1.

THE following course of lecture-demonstrations will take place at the St. James' Hospital, Ouseley Road, Balham, S.W., under the auspices of the South-West London Post-

Graduate Association: October 24th, the nervous child, Dr. Hector C. Cameron; November 1st, skin diseases common to animals and man, Dr. W. J. O'Donovan; November 6th, radium therapy, Mr. V. Zachary Cope; November 13th, demonstration of cases, Dr. Charles E. Lakin; November 20th, contraception technique, Dr. Norman Haire; November 27th, the ophthalmoscope in general practice, Mr. Maurice Whiting; December 3rd, disorders of the menopause, Mr. Leonard E. Phillips; December 11th, modern methods of diagnosis of rectal diseases, Mr. E. T. C. Milligan. Each lecture-demonstration will begin at 4 p.m. Particulars as to membership, etc., may be had from the honorary secretary, Dr. R. J. Saunders, 10, Lyford Road, Wandsworth Common, S.W.18.

THE Right Hon. Christopher Addison, M.D., Parliamentary Secretary to the Ministry of Agriculture, will, it is understood, be the chairman of the body to be set up by the Government to inquire into the fishing industry in Great Britain.

THE Minister of Health has appointed Mr. R. J. Simpson to be an Assistant Secretary of the Ministry.

THE Society of Apothecaries celebrated Master's Day on October 4th with a service at St. Andrew's-by-the-Wardrobe, followed by the usual Master's dinner at the Apothecaries' Hall. Special interest was lent to this occasion by the fact that for the first time for many years the outgoing Master, Lieut.-Colonel C. T. Samman, in recognition of his services to the society, was placed in office for a second term.

DR. W. ALLEN DALEY, the medical officer of health for Hull, on leaving Hull to become a principal medical officer of the London County Council, has been presented by the members of the staffs of the Health, Maternity and Child Welfare, and School Medical Departments of the corporation, and of the Hull and Goole Port Sanitary Authority with a grandfather clock. Dr. Daley also received silver cigarette boxes from the chief officials of the corporation, and an expanding book support from the motor car watchers employed under the scheme inaugurated by him for the assistance of ex-sanatorium patients.

A LARGE number of members and guests of the Surgical Instrument Makers' Association attended the annual dinner at the Holborn Restaurant on October 11th. The president of the association, Mr. Patrick C. Maw, of Messrs. S. Maw, Son and Sons, Ltd., was in the chair, and the principal guest was Mr. Charles Goulden, F.R.C.S. Mr. L. Ferris-Scott, Financial Secretary and Business Manager of the British Medical Association, who was to have been one of the guests, was unable to be present. The toast of "The Association" was proposed by Mr. H. E. Curtis, J.P., and supported by Mr. A. W. Down, a former president, who remarked that the one great object of the association was to maintain the high character of the work turned out by the manufacturers of this country. Although foreign competition could not always be fought successfully in the matter of price, it could always be met in the matter of quality. The association had been very active in its endeavours to get an order for all foreign instruments to be marked on importation, so that surgeons might know where they had been made. The Merchandise Marks Act Committee in their report appeared to be convinced of the soundness of the manufacturers' case, but to feel that this was rather a small trade in volume, and that marking would impose difficulties upon the excise officers. All that the manufacturers had been able to obtain from the committee was a recommendation that instruments should be marked on sale. In thanking the association for its hospitality, Mr. Goulden remarked on the opportunity he had at that dinner of meeting many whose names had been familiar to him for years in connexion with the instruments he commonly employed. The names of some firms of instrument makers were household words in the medical profession, and it was a great pleasure to see their living representatives.

THE Minister of Health and the Minister of Transport received a deputation, on October 15th, from the London County Council upon the question of the proposed Battersea Power Station. The deputation was introduced by the chairman of [illegible] Bretton. Dr. Barrie Lambert, chairman [illegible] Committee, set out the views of the council on the erection of the station, and drew attention to resolutions passed by the council, indicating that in its opinion every possible endeavour should be made to secure that the most efficient measures were adopted to prevent any nuisance or menace to health, particularly from the emission of sulphur fumes, and that the efficacy of the measures should be thoroughly tested in actual working over a sufficient period before any further new electricity stations or enlargements of such stations in London were authorized. The Minister of Health and the Minister of Transport, while indicating in their replies that they could not be indifferent to electrical needs, stated that the Government would certainly insist upon everything practicable being done for the protection of the public.

THE Colyer Prize was founded by the Section of Odontology of the Royal Society of Medicine in June, 1926, to commemorate the twenty-five years' service of Sir Frank Colyer as honorary curator of the Odontological Museum. The accumulated income of this fund may be used every third year for the purpose of awarding a prize for the best original work in dental science completed during the previous five years by a dental surgeon educated at any recognized dental school in Great Britain or Northern Ireland who has not been qualified to practise more than five years at the date of the award. Applications from candidates for the first award should be submitted not later than March 31st, 1932, together with a general account of their researches, both completed and in progress. A document declaratory of the award will be presented with the prize, the value of which is about £35. If no work of sufficient merit is submitted the prize will not be awarded.

A CONFERENCE on maternal mortality will be held on Tuesday afternoon, October 22nd, at 2.30, in the Central Hall, Westminster. A report on its work will be presented by the Maternal Mortality Committee, and consideration will be given to the report of the Departmental Committee on the Training and Employment of Midwives. The speakers will include the Minister of Health and Lady Barrett.

THE council of the Midwives' Institute has issued a statement welcoming the report of the Departmental Committee on the Training of Midwives, in so far as it recommends schemes for making available, for all mothers, skilled attention and nursing care at the time of childbirth. While recognizing that many of the recommendations of organized midwives have been accepted by the committee, the council views with strong disapproval the suggestion that the control of the training and curriculum for midwives should be taken over by a Government department, thus eliminating the principle of self-government and self-development that is accorded to all other professions. It considers that the withdrawal of control from a specialized body on which organized midwives have definite representation and powers, would lower the standard of the profession and lessen its attraction for the most suitable women to undertake the responsible part in the struggle against maternal mortality assigned to midwives by the departmental committee.

ON October 4th, at a well-attended meeting of medical practitioners in the county of West Lothian, Dr. John Keay was presented with a fine mahogany bureau as a token of affection for himself and in appreciation of his services to the profession as chairman of the local panel and medical committees during the past seventeen years.

UNDER the auspices of the Industrial Health Research Board a report entitled *A Study of Personal Qualities in Accident Proneness and Proficiency*, by Messrs. Eric Farmer and E. G. Chambers, has been published by H.M. Stationery Office, price 3s. net. The authors, who previously conducted a research into the personal factors involved in the causation of accidents in six groups of workers (see *Journal*, 1926, vol. ii, p. 1132), have now investigated the conditions in respect of 1,800 apprentices in the workshops of certain Naval and Royal Air Force establishments. They conclude that industrial proficiency with proneness to accidents depends on many dominant factors, and not upon one only; the tests on which the estimation is based, while applicable to some of these factors, do not necessarily measure the most important of them. The authors believe, however, that even at the present stage the general use of certain of the tests described would result in the selection of entrants more capable of benefiting by instruction and less liable to accidents.

THE seventy-sixth meeting of the Swiss Society of Psychiatry will be held at Basle, in conjunction with the Association of Psychiatrists of South-West Germany, on October 26th and 27th, when there will be a discussion on the primary and secondary symptoms of schizophrenia, introduced by Professors E. Bleuler of Zürich and Mayer-Gross of Heidelberg.

THE thirty-fifth congress of the Italian Society of Internal Medicine will be held at Genoa from October 23rd to 26th, when [illegible] ts will be discussed: haemolytic [illegible] by Professor Ferdinando Micheli; [illegible] of the respiratory system, introduced by Professors Giovanni Boeri and Iginio Jacono; spontaneous gangrene of the limbs with special reference to endarteritis obliterans, introduced by Professors Guglielmo Scala and A. Ciminata; chronic lesions of the respiratory tract and military service, introduced by Lieut.-Colonel Gino di Logu. The secretary is Dr. Michele Manara, R. Clinica Medica, Via Balilla 5, Genoa.

AT the close of the recent congress of French-speaking dermatologists and syphiligraphers the presidents, Dr. Sabouraud, was presented with a medal by his friends and pupils.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863, and 9864 (internal exchange, four lines).*

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the *British Medical Journal, Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

Treatment of Glandular Deficiency in a Child.

DR. L. S. WOOLF (London, N.W.) wishes to hear of a school in the country for a child suffering from a slight degree of glandular deficiency, where she would have good medical treatment and also plenty of fresh air while being taught the ordinary school subjects.

Fleas.

"W. G. H." writes: I should be very grateful if some reader of the *British Medical Journal* could suggest a satisfactory method of protection against fleas. In a working-class practice I frequently pick these parasites up and carry them home. One member of my household is hypersensitive to their bites. They form vesicles and afterwards running sores, which do not heal for some days.

Hot Feet at Night.

DR. F. LILLEY (Weston-super-Mare) invites suggestions for the relief of feet becoming so uncomfortably warm about two hours after going to bed that they have to be kept outside the bedclothes for the remainder of the night, thus preventing sleep. The rest of the body is quite normal. His patient is about 60 years old, and is otherwise quite healthy.

Treatment of Chilblains.

DR. C. DE Z. MARSHALL (*Hampton, Middlesex*) *writes*: I have found that potassium citrate will rapidly cure most cases of chilblains, and the worst cases are markedly alleviated and eventually cured. Pot. citr., sod. bicarb., āā gr. x, with inf. gent. co., t.d.s., a.c., is the mixture I have been in the habit of giving, and I have heard of no failures. Mild cases are cured in three days. I shall be glad to hear the experiences of others.

Income Tax.

Capital or Revenue Expense.

"J. E. P." formerly garaged the car used professionally at a cost of 10s. per week, but has now erected a garage at a cost of £90, thus saving the future expense of outside garaging. The inspector states that, though the 10s. per week was allowable, the outlay of £90 cannot be allowed.

*** That is correct. The £90 represents an expenditure of capital—that is, an outlay for *future* benefit, and under the Income Tax Acts cannot be deducted in calculating the liability.

Cessation of Employment.

"MARTHA" was superannuated from July 15th, 1929, with a pension of £150 a year, and has been informed that for the financial year ending April 5th, 1930, he will be assessed on the amount of his income for the year to April 5th, 1929.

*** This is incorrect. Section 45 (5) of the Finance Act, 1927, provides that "where in any year of assessment a person ceases to hold an office or employment . . . tax shall be charged for that year on the amount of his emoluments for the period beginning on the 6th day of April in that year and ending on the date of the cessation." The effect of this is that for the year ending April 5th, 1930, our correspondent will be chargeable, so far as his emoluments and pension are concerned, on the amount of his income for that year.

Visit to the United Kingdom.

"B. V. C." arrived in this country from abroad on May 19th, 1929, for a holiday till March 15th, 1930. Is he liable to income tax?

*** If he spends six months in the United Kingdom during the year ended April 5th, 1930, he will be liable to account for tax on the amount of his foreign income—less the usual personal allowances, children allowances, etc. If, therefore, it is necessary for "B. V. C." to avoid that liability, he can do so—as he suggests—*by spending part of his holiday outside the United Kingdom*, but "three weeks or a month" will not be enough; he will have to spend a period of nearly five months in that manner.

LETTERS, NOTES, ETC.

Disclaimer.

ON October 2nd a London daily newspaper published an alleged interview between one of its reporters and a Dr. F. C. Keith, described as borough medical officer for Bethnal Green. Dr. F. C. Keith, formerly medical officer of health for Bethnal Green and now medical officer of health for Deptford, informs us that the alleged interview did not take place with him, and that he has addressed a disclaimer to the editor of the newspaper in question.

A Word to the Wise.

DR. H. I. DAVIES (London, W.2) writes: For the benefit of my colleagues I should like to call attention to the fact that there is abroad in London an individual whose symptoms and signs are interesting enough to engage attention, but whose bank account appears to be non-existent. She is about 40, short, plump, and dark, with blue eyes and a slight moustache; her history is one of mastoid disease and a severe intracranial operation on the right side, and the signs bear this out, showing in addition a hysterical hemiparesis and hemianaesthesia on the right. Apart from interest in an unusual case, practitioners would be wise not to waste their time or risk their money upon her.

Medical Golf.

THE autumn meeting of the Medical Golfing Society was held at Deal on the Royal Cinque Ports golf course on October 12th and 13th. The weather was delightful and the course in grand order, both greatly enjoyed by over 70 members. The selling sweep dinner was held at the South-Eastern Hotel, where nearly all the members stayed. The competition results were as follows:

Singles v. Bogey.—Cland Apperley, 2 up, after a fourfold tie with Sir Milsom Rees, G. F. Wilson, and J. Pringle.

Foursomes v. Bogey.—J. Pringle and J. Collins, all square.

Canny Ryall Cup.—C. V. Mackay, 84 − 12 = 72; A. Galletly, 75; D. A. Davies and C. Max Page, 77.

THE autumn meeting of the Shropshire Medical Golf Association was held at the Wrekin Golf Club on Sunday, October 13th. The competitions were: Morning, eighteen holes medal play for the captain's prize, presented by Dr. Aubrey Ireland (Shrewsbury). This was won by Dr. G. D. Wedd, with the fine net score of 68.

G. D. Wedd, 85−17=68; W. R. Pooler, 84−15=69; H. G. Beckett, 80−10=70; T. R. Elliott, 79−6=73; J. Lavelle, 85−12=73; A. Mackenzie, 82−8=74; D. Max, 89−14=75.

In the afternoon the foursomes v. bogey was won by Dr. Wedd and Dr. Harker, 2 down; Dr. Ireland and Dr. Elliott were 3 down; Dr. Mackenzie and Dr. Lavelle, 4 down; and Dr. Richardson and Dr. Beckett, 5 down. Dr. Ireland presented the prizes, and Dr. Clarke (Newtown) was elected captain for the ensuing year, and Dr. T. R. Elliott honorary secretary. The next meeting was fixed for the last Sunday in May, 1930, at Church Stretton.

Precautions against Skidding.

THE SECRETARY of the Automobile Association writes: After an abnormally fine summer it is highly probable that there will be many drivers of motors with but limited experience in guarding against skidding. The following hints, suggested by the A. A., may be of use now that wet weather has set in: (1) Carefully examine tyres and, if necessary, get new ones, so as to obtain the full benefit of the antiskid tread. (2) The brakes should be thoroughly overhauled and balanced. (3) When driving on greasy or wet roads set a moderate pace, and avoid violent swerving or braking, and sharp cornering. (4) Allow a longer distance in which to pull up. (5) Be specially careful on roads with a steep camber or slope. (6) Some forms of road surface are more slippery than others; be careful when passing from one to another. (7) Tree-shaded roads often have a very treacherous surface of rotting leaves in the gutters. (8) If inexperienced in how to correct a skid, take some lessons from an expert. (9) Avoid "cutting-in" or "cutting-out," and be very careful, especially with motor cycles, when crossing tram lines. (10) Give more road space to cyclists, and avoid forcing them towards steep gutters.

Vacancies.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 54, 56, 57, 60, 61, 62, 63, and 64 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 58, 59, and 60.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 179.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

327. Diabetic Endarteritis.

L. LETULLE, M. LABBÉ, and J. HEITZ (*Arch. des Mal. du Coeur*, uly, 1929, p. 449) introduce some pathological studies of a ase of diabetic endarteritis by reference to its previously stablished features. This disease affects principally the ıost peripheral vessels and is unattended by much throm-ıosis, the obliteration of the lumen being due entirely to ıtimal proliferation. The latter shows infiltration with holesterin and sometimes hyaline degeneration. In the nedia there is degeneration with diffuse or local calcifica-ion, while the adventitial tissues show little or no change. The formation of new arterial and venous channels to take he place of the obliterated vessel has been observed to occur n the media, and sometimes in the intima, as a sequel to nflammatory processes. Such new channels are so rare in ırterial disease of diabetic origin that the authors have given ı full description of the clinical and pathological changes bserved in their patient. A woman, aged 60, after suffering or fifteen years with diabetes, was found to have gangrene of the foot, which subsequently necessitated amputation. Microscopical examination of the arteries showed that although the femoral, anterior tibial, and dorsalis pedis were affected in varying degree, the posterior tibial had suffered most. In the proximal part of this vessel, although the lumen was not quite obliterated, spaces lined with endothelium and filled with blood were seen in the deeper layers of the intima. Lower down none of the natural lumen remained; small, newly formed venules were observed as in the more proximal parts of the vessel, but in addition a new formation of arteries had occurred in the substance of the proliferated intima. These minute vessels possessed elastic layers and muscle fibres with well-marked nuclei, in addition to an endothelial lining. The authors attribute the rarity of these appearances to the lack of reconstructive power in a tissue the seat of advanced degenerative changes.

328. Diabetes Mellitus and Arterio-sclerosis.

K. W. ANDERSON (*Minnesota Med.*, August, 1929, p. 484) comments on the increasing interest in the question of the interrelationship of diseases of metabolism and those of the degenerative type, particularly in connexion with arterio-sclerosis and diabetes. Clinically, it is often difficult to distinguish cause from effect, particularly in the older diabetics, in whom the commencement of diabetes appears to coincide closely with the age of the onset of arterio-sclerosis. Anderson reports the case of a man, aged 33, in whom diabetes mellitus preceded by ten years the symptoms of degenerative disease. The patient at the age of 19 began to suffer from intractable boils and carbuncles; these persisted for three years, when glycosuria was discovered and a diagnosis of diabetes mellitus was made. Dieting without insulin controlled the disease. At the age of 26 he contracted syphilis and received energetic treatment for two years, when he had to cease work on account of debility; he could not then live on his regular diet. He was admitted to hospital and treated with insulin and dieting. On discharge the urine contained neither sugar, diacetic acid, nor acetone. Two years later he noticed slight oedema of ankles, and after some months was again obliged to stop working. The urine then contained 8 per cent. sugar, many hyaline casts and erythrocytes, occasional leucocytes, and acetone, but no diacetic acid. The Wassermann reaction was negative. The glycosuria disappeared with dieting, but progressive cardiac failure terminated fatally a month after readmission, in spite of the exhibition of diuretics and digitalis. The heart was very dilated and there was evidence of generalized arterio-sclerosis, especially in the retinal and coronary arteries. This patient had diabetes for fourteen years, but it became less severe with advancing age, although the arterio-sclerosis progressed rapidly during the three years that elapsed between the first and second admissions to hospital. Anderson quotes Joslin's observation that diabetics age prematurely, as is shown by increased arterio-sclerosis. Other authors have recorded arterio-sclerosis revealed by skiagrams in 63 per cent. of diabetics above the age of 40, while in 121 non-diabetic patients of similar ages only 28 per cent. showed arterio-sclerosis. Another writer has reported that arterio-sclerosis is more severe and frequent in diabetics than in non-diabetics of the same age-group. Aortic sclerosis was always present in diabetics over 50 years of age. Anderson does not think that syphilis was an important factor in this case; but many writers have assumed that the heavy metals used in antisyphilitic treatment predisposed to premature arterio-sclerosis. One interesting observation made was that the pancreas in this case appeared to be normal, and the arteries did not show any extensive changes.

329. Bronchial Asthma.

DISCUSSING the pathogeny and treatment of bronchial asthma and its anaphylactic nature, HAIBE (*Rev. de Méd.*, 1929, No. 6, p. 623) maintains that, contrary to the old conceptions, the bronchitis is now considered to be the cause, not the result, of the asthma, and that at its onset the latter disease reveals a pulmonary lesion, often insidious, and apparent only by *x*-ray examination. This lesion, termed by Besançon and Dejong the "pulmonary thorn," dominates the whole pathology of bronchial asthma, and many diseases predispose to its causation, such as rhinitis, rhino-tracheitis, coryza, and tracheitis. While tuberculosis and syphilis are rarely responsible for true asthma, in numerous cases the pulmonary lesion is of bacterial origin and terminates in asthma in subjects capable of being sensitized to the corresponding toxins. Streptococci, particularly of the haemolytic type, and staphylococci are the most frequent causal factors of the rhino-tracheo-bronchitis, and their proteins sensitize predisposed persons. In treating these cases Haibe recommends the use of autogenous vaccines, the dosage of which is governed by the degree of the reactions produced. Owing to local reactions, and in order to avoid a local refractory condition, it is advisable to utilize a fresh site for each injection. Better results are obtained by first injecting into the pre-thoracic region, then into the interscapular space, and finally into the limbs. As an adjunct in cases complicated by rhino-pharyngitis, antivirus therapy is advised, the filtrates being prepared according to Besredka's method. This is instilled into each nostril three or four times daily. Since asthma is essentially a recurring disease, vaccine treatments should be given before autumn and at the beginning of spring in order to prevent recurrences. Haibe claims to have obtained cures in 90 to 95 per cent. of cases in children, adolescents, and adults with a recent infection; in old cases cure results in only 40 to 45 per cent. K. D. FIGLEY (*Amer. Journ. Med. Sci.*, September, 1929, p. 338) reports four cases of asthma due to may-flies; the disease had been caused by the inhalation of minute particles of the shed pellicle of these insects. One patient was successfully treated with an extract of dried may-flies. It is thought possible that these widely distributed insects may be sensitizing agents.

330. Post-vaccinal or Vaccinal Encephalitis.

A. NETTER (*Bull. de l'Acad. de Méd.*, July, 1929, p. 30) reviews the literature and states that he has collected twenty-one French cases of encephalitis following vaccination, the first of which were published in October and November, 1926, and May, 1927, by Comby, Huber, and Dénechau. He favours the substitution of the term "vaccinal" for "post-vaccinal" encephalitis on the following grounds: (1) Calmette and Guérin found the virus in the nerve centres of vaccinated rabbits; (2) A. Marie, followed by Levaditi and his collaborators, showed the possibility of producing a vaccinal encephalitis in the rabbit; (3) in a case recorded by Fracassi and Cuestas a generalized vaccinal eruption was associated with encephalitis. This view, which was advanced by Netter in 1925 and accepted by Leiner in 1926 and Jorge in 1927, was rejected by the Dutch physicians as well as by the Andrewes and Rolleston Committees and the League of Nations Committee, owing to the negative results obtained by Levaditi, Biji, and Kraus. Netter, however, maintains that the positive results are of much greater value than the negative results, which may be explained by rapid disappearance of the virus from the brain by a process of auto-sterilization. In conclusion, Netter emphasizes the extreme rarity of encephalitis when the number of uncomplicated cases of vaccinations are taken into account, and urges that their occurrence should not contraindicate the performance of such an effective safeguard against small-pox.

331. Lederer's Anaemia.

T. CHRISTIANSEN (*Acta Med. Scand.*, August 21st, 1929, p. 472) discusses a form of haemolytic anaemia which was first described by Lederer. It is an acute, probably toxic, anaemia manifesting a megaloblastic blood cell regeneration and a raised colour index. Unlike pernicious anaemia, there is a high leucocyte count which may be over 50,000 per c.mm., and the polymorphonuclear leucocyte percentage

may be over 80, many being young cells; myelocytes are commonly present. The illness has an acute onset with fever and slight icterus; there is a rapid fall in the haemoglobin percentage and red cell count. The red cells are said to be normal in shape and size; megaloblasts and enormous numbers of normoblasts (up to 3,000 per c.mm.) have been noted. The condition is not associated with glossitis, achylia, or nervous symptoms. Transfusion gives immediate relief, and the patient makes a complete recovery. Apparently only five cases have been recorded. One of these was treated by Christiansen with liver. Before the treatment was started a spontaneous increase in the reticulocytes occurred, suggesting the onset of a remission. Liver diet had no influence on the percentage of these cells, and there was no reaction fall in their number; the red cells were unaffected, though the *haemoglobin percentage was raised. A normal red cell count* was only re-established after the liver treatment had been discontinued for a long time.

332. Pemphigoid Varicella.

P. GAUTIER and A. THEVENOT (*Rev. Franç. de Péd.*, June, 1929, p. 363), who record an illustrative case in a boy, aged 2 years, who recovered, remark that the existence of a pemphigoid or bulbous form of varicella was disputed by Leredoullet and David and their pupil Lebis in 1927, on the ground that the cases hitherto published were either examples of simple pemphigus or cases of pemphigus accidentally associated with varicella. The present case, however, was not an example of epidemic pemphigus or of pemphigus associated with varicella, but was a classical instance of the pemphigoid form of varicella, in which the lesions, which were at first typical of varicella, subsequently assumed a *pemphigoid appearance. Moreover, the authors add, if the* case had been one of pemphigus only the patient would undoubtedly have contracted varicella from the other patients in the ward, where he remained more than a month. Pemphigoid varicella does not appear to be due to secondary infection of the vesicles, since repeated cultures of the serum of the bullae always remained sterile; nor is it caused by an enhanced virulence of the causal organism of varicella, since a pemphigoid varicella may give rise to an ordinary attack, as in the present case, in which the pemphigoid patient infected his brother, who had an ordinary attack of varicella. On the other hand, the authors hold that the supposed epidemics of pemphigoid varicella were probably epidemics of pemphigus.

Surgery.

333. Ligation in Thrombo-Angiitis Obliterans.

G. W. VAN GORDER (*Annals of Surgery*, July, 1929, p. 88) reviews nine cases of thrombo-angiitis obliterans in which high ligation of the main vein of the extremity was employed with good results. This disease of the blood vessels is one in which arterial occlusion predominates, and in cases of thrombo-angiitis obliterans the collateral circulation is the most promising key to the solution of gangrene prevention. *Of the nine cases under review, in five the femoral vein was* tied at the apex of Scarpa's triangle, and in the same number of cases the external iliac vein was ligatured just distal to the bifurcation of the common iliac. In two instances obliterated femoral arteries were also cut; in one of these ligation of the left basilic and brachial veins was performed, and in the other the saphenous vein was tied, together with the femoral vein. Three of the first five cases definitely improved; there was cessation of the gangrene, but slight residual pain in one, *and failure to relieve* symptoms in one. In the five cases with external iliac vein ligations, there was disappearance of pain and cessation of gangrene in three, relief from pain but not from gangrene in one, and no improvement in the fifth until the tip of a gangrenous toe was removed. The two cases in which section of the obliterated femoral artery was performed in addition to vein ligation to relieve pain were failures, as was also the case in which the saphenous vein was tied together with the femoral vessels. Ligation of the basilic and brachial veins was successful in one case. Thus, of nine cases treated by high ligation of the vein, there was marked improvement in six, some improvement in two, and no improvement in one; this suggests that if the disease is arrested even temporarily by this method of treatment, the most reasonable explanation is on the basis of an improved collateral circulation. High ligation of the main vein offers a marked resistance to the outflow of blood and an increased venous and capillary pressure, which directs a greater volume of *collateral blood* from the normal arteries of the limb into anastomosing channels that will eventually reach the distant capillary bed. It is concluded that the procedure is of definite value in giving relief from pain, in combating impending or advancing gangrene, and in postponing or obviating high amputation.

334. Bilateral Renal Calculi.

C. BORETTI (*Urol. and Cut. Rev.*, July, 1929, p. 460), who records eighteen personal cases, of which only five were fatal, states that of 300 operations for renal and ureteral lithiasis by Professor Lasio at the Ospedale Maggiore, Milan, 16 per cent. were for bilateral calculi. Such cases are more frequent in men (66.67 per cent.). The earlier the diagnosis the better the prognosis will be, deaths being usually due to an exacerbation of pre existing uraemic conditions in patients who have come under treatment too late. The diagnosis must be founded on radiography and sometimes pyelography. The functional condition of the kidneys must be determined separately and conjointly by bilateral catheterization, Ambard's constant, and the phenolsulphonephthalein test. As bilateral renal surgery must be ultra-conservative, Boretti recommends pyelolithotomy, by which all kinds of stones can be extracted from the pelvis and also from the calyces. Where, however, there are several small stones situated in the calyces or in the parenchyma they should be removed by small and, if necessary, multiple incisions, guided by an exploratory needle. It is always best to begin with the kidney which functions best. Nephrectomy is an operation which should seldom be performed. Permanent nephrostomy *should be preferred when one is not sure about the efficiency* of the other kidney.

335. Pyrexia in Malignant Disease.

G. TIZIANELLO (*Il Policlinico*, Sez. Med., September 1st, 1929, p. 452) remarks that the pathogenesis of fever occurring in connexion with new growths has long been the object of discussion, having first been described by Wunderlich; no *adequate explanation, however, of it has yet been offered.* During the period 1921–26 118 cases of various tumours were treated in the medical department of the Civil Hospital of Venice, their distribution being as follows: digestive system 85; brain 13; larynx, mediastinum, lungs, and pleurae 8; urogenital system 8; glandular and osseous systems 2 each. Of the 118 cases, 43 were accompanied by fever and 75 were always apyrexial. Communication with the exterior does not appear to be an important factor in the development of fever, since the proportion of febrile cases was not higher in the case of the digestive system (36.47 per cent.) or the urogenital system (12.50 per cent.) than in the case of cerebral tumours (12.50 per cent.). This fact, therefore, controverts the view that neoplastic fever is due to secondary infection. Moreover, the tumours are completely shut off, and are capable of themselves of giving rise to fever. Of 17 cases examined histologically by Tizianello, 8 were accompanied by fever; 2 of these were examples of epithelioma, 4 of adenocarcinoma, and 2 of endothelioma. No relation was discovered between the existence of fever and the activity of cell division, necrosis, caseation, or metastasis. Tizianello concludes, therefore, that no connexion can be demonstrated between the presence of fever and the histological type of growth.

336. Congenital Scoliosis.

C. ROEDERER and H. DIJONNEAU (*Paris Méd.*, September 21st, 1929, p. 240) suggest that to limit the term "congenital" to scolioses that are apparent only at birth is somewhat inexact, and that this condition, if late in producing its effects, in none the less always pre-n [illegible] postulated by Roederer and Mouchet in [illegible] congenital scoliosis as a late[illegible] by an embryonic or foetal [illegible] on one or more parts of the vertebral column. This elementary alteration terminates, according to its importance and quality, either in a malformation of one bone or of some vertebral elements (the bo[illegible] or in a more extensive inequality of [illegible] involving the whole column. The various types of scolioses, those without and those with osseous vertebral anomalies, and spina bifida accompanied by scoliosis; they record cases illustrating each type. The chief characteristics of congenital scoliosis are the following: the paramedian, irreducible, osseous gibbosity; rigidity of the spine; and the absence of all pain, either spontaneous or provoked. A sharp inflexion in the line of the spinous apophyses is often present, and sometimes at the inflexion is felt a deep depression, the spinous foramen of Gourdon, which is characteristic of congenital scoliosis with spina bifida. Radiography is indispensable in diagnosis, and three plates are advisable—namely, full face, in profile, and oblique. The treatment of scolioses is unsatisfactory, since *the cause cannot be remedied. The sole aim must be to* create, above and below the abnormal point, compensatory curvatures, which will still permit free functioning of the thoracic and abdominal [illegible] Patients should be constantly watched, [illegible] nenace intervention should be practised. [illegible] on its back in a hypercorrected

plaster cast. When old enough to walk, corsets of reinforced duck for very young infants, or of celluloid for older ones, should be used. Corrective gymnastics should be instituted, and appropriate medical treatment favouring growth (saline baths, lime salts, iodine, etc.) should be given. The authors consider that a congenital scoliosis with perceptible anomalies is less grave than one without these, than a pleuritic or paralytic scoliosis, and even than a juvenile rachitic scoliosis.

337. Congenital Malformations of the Hip.

J. GOURDON (*Gaz. Hebd. des Sci. Méd. de Bordeaux*, September 8th, 1929, p. 566) maintains that the term "congenital luxation of the hip," to designate the affection which characterizes the claudication of cripples, is erroneous. The luxation is not congenital and is produced only when the child commences to stand—that is, when it is about 16 to 20 months old. At birth the only malformations which exist are those which permit femoral displacement by the force imparted from below upwards in the erect position; such are arrested development of the cotyloid cavity, vertical direction of the pelvis, and atrophy and abnormal direction of the upper extremity of the femur. An early diagnosis of these conditions is desirable, before articular dislocation supervenes, when treatment becomes difficult and prolonged and the results are less certain. Gourdon employs the following diagnostic method in every infant who, without any symptom of paralysis, presents an abnormal mobility of the hip which can only be attributed to malformations of the coxo-femoral articulations. The patient is laid on a table and reclines on the sound side. The thigh of the affected side is horizontally flexed and adducted till the knee rests on the table. The leg is then flexed at right angles to the thigh, and, this position being maintained, the lower end of the femur is slowly rotated inwards. If this movement is arrested when the leg is raised not more than 60 degrees above the table the hip is normal; if the elevation exceeds 70 degrees there is articular relaxation; and if it reaches 90 degrees malformations of the cotyloid cavity are present. Internal hyperrotation is an efficient treatment for restoring the cotyloid cavity to its normal state; it is sufficient to place the thigh in abduction at right angles for a quarter of an hour three times daily. The child should be allowed to assume the upright position only after four months of this treatment. Gourdon reports excellent results from this method in all cases that he has followed.

338. Vesical Calculus and Enlarged Prostate.

G. MILLUL (*Il Policlinico*, Sez. Chir., July 15th, 1929, p. 365) records fifteen cases of vesical calculi in patients suffering from enlarged prostate and retention. He remarks that it is not always easy to diagnose the presence of calculi from symptoms alone, though certain symptoms are suggestive of their presence. In the prostatic patient who has calculi but no great amount of residual urine, pain on micturition comes on towards the commencement of micturition rather than at the end; it is aggravated when the contractions of the bladder are frequently repeated, or when the bladder is partly emptied and the stone irritates the bladder wall. Haematuria of the vesical type, brought on by movement and ceasing during repose, is suggestive. The safest way to establish the diagnosis is to radiograph the bladder. In all the author's cases the calculus was of local origin, and there was no evidence of any renal stone. Catheterization, lavage, infection, and retention of urine are each likely to originate a calculus.

339. Senile Gangrene.

W. SAMPSON HANDLEY (*Journ. Coll. Surg. Australasia*, July, 1929, p. 38) describes his experience with periarterial alcohol injections in the treatment of threatened senile gangrene as compared with arterial sympathectomy. In the latter procedure a certain length of the outer coat of the artery is stripped off, thus interrupting the sympathetic nerves running thereon, and producing a vaso-dilator action on the parts below. A local contraction of the artery occurs, so that a low circulation, lasting for a time up to fifteen hours, precedes the onset of the vaso-dilator symptoms, which eventually supervene for three or four weeks. Such an initial vaso-constriction may be very dangerous in threatened gangrene, and the period of subsequent vaso-dilatation is too short to permit separation of the toes or of a portion of the foot. In periarterial alcohol injection there is no initial period of diminished circulation, vaso-dilatation being produced at once without any local contraction of the artery at the site of injection, and without any temporary aggravation of the condition. The method is useless in thrombo-angiitis obliterans, and in cases in which the temperature of the gangrenous foot is higher than that of the sound foot; in Raynaud's disease, however, and in infantile paralysis with capillary congestion, it may avert a more serious procedure and produce some degree of improvement. The author adds that in cases with signs of threatened gangrene the procedure should be employed before actual gangrene has occurred, or while it is still confined to a small area.

340. Acute Glanders.

J. W. ROELOFFS (*Nederl. Tijdschr. v. Geneesk.*, July 13th, 1929, p. 3272), who records an illustrative case of acute glanders, illustrates the rarity of both the acute and chronic forms of the disease by the fact that the last instance in Holland was recorded in 1913 by Van der Valk and School, who published a case of chronic glanders. The present patient was a laboratory attendant, aged 33, in whom the disease developed after an incubation period of a few days, with symptoms of septicaemia. At the end of a fortnight he developed a characteristic rhinitis with a sanious discharge, typical lesions in the skin and mucous membranes in the form of small bluish nodules which rapidly broke down, and typical foci in the lungs, as well as non-specific infiltration. Treatment consisting of intravenous injections of 5 c.cm. of 2 per cent. solution of trypaflavine was of no avail, and the disease ended fatally in nineteen days. Glanders bacilli were found in the blood, pustules, and throat mucus.

Therapeutics.

341. Therapeutic Vasotrophic Shock in Asthma.

ACCORDING to G. BOUCHÉ (*Le Scalpel*, August 17th, 1929, p. 889) the typical lesions of the respiratory tract found in asthma should not be considered causal, since they are frequently present in non-asthmatic cases such as bronchial and nasal catarrh or emphysema. With regard to the physiological pathology, he rejects the hypotheses of direct vagus irritation (although admittedly this is found in rare cases associated with wounds) and of excessive carbonaemia, and he holds that the immediate cause is vasotrophic shock associated with parasympathetic irritation, in the second stage of which a rise of the blood pressure occurs. The agents of shock are innumerable, and any one may precipitate the irritation. Individual variation may determine lesions of this irritation to one particular system; for example, damage of the lungs by gaseous irritants may lead to its manifestation in bronchial asthma. The shock is not necessarily anaphylactic; Bouché admits that occasionally sensitiveness to one particular protein may cause asthma, but he does not practise routine search for any one cause. His method of treatment is to inject substances producing shock, in amounts giving a minimum of local and general reaction; such substances are the serums, crotalin, and vaccines, the stock varieties being found as efficacious as the autogenous. He remarks that asthmatic patients usually react violently; it is therefore wise to use serums diluted 1 in 10 in doses of about 1 c.cm. Some patients are hypersensitive to serums, and crotalin or vaccines are preferable; patients with tuberculous lesions are particularly sensitive to serums. Doses sufficient to precipitate crises should be avoided, and they should be diminished also during periods of respiratory excitation. Treatment should be continued for eighteen months to two years after the subsidence of attacks. Bouché recognizes two main varieties of tractable cases. In hay fever the treatment should be begun two months before the "season" and be continued to its end; in this class he has had only one failure in twelve cases. As regards the nervous type of asthma, the author states that he has no experience of treating patients with gross pleural lesions or continual bronchitis, but he does not exclude from treatment those with small inactive apical lesions. He defines three stages of treatment as follows. (1) In the course of the first six or seven injections the patient's degree of sensibility is determined and an appropriate dosage evolved; sometimes improvement is noticed from the first dose. (2) The reactions become fixed or gradually less. Attacks become less frequent and more amenable to palliation; the length of this period is variable. (3) The crises disappear, but the treatment should be continued for a period ranging from some months to two years. Of 17 cases treated by the author he claims twelve complete cures of varying duration and three temporary ameliorations; he admits two complete failures in patients who could not tolerate the initial reactions. He thinks that the treatment of patients with [illegible] is too risky to be worth attempting. With [illegible] he suggests that it is always w[illegible] of the injection, but that the success of any substitute one almost always empirical, prolonged search for a specific one being waste of time. In associated "shock lesions," such as urticaria with asthma, it is noteworthy that one lesion may

may be over 80, many being young cells; myelocytes are commonly present. The illness has an acute onset with fever and slight icterus; there is a rapid fall in the haemoglobin percentage and red cell count. The red cells are said to be normal in shape and size; megaloblasts and enormous numbers of normoblasts (up to 3,000 per c.mm.) have been noted. The condition is not associated with glossitis, achylia, or nervous symptoms. *Transfusion gives immediate relief, and the patient makes a complete recovery. Apparently only five cases have been recorded. One of these was treated* by Christiansen with liver. Before the treatment was started a spontaneous increase in the reticulocytes occurred, suggesting the onset of a remission. Liver diet had no influence on the percentage of these cells, and there was no reaction fall in their number; the red cells were unaffected, though the haemoglobin percentage was raised. A normal red cell count was only re-established after the liver treatment had been discontinued for a long time.

332. Pemphigoid Varicella.

P. GAUTIER and A. THEVENOT (*Rev. Franç. de Péd.*, June, 1929, p. 363), who record an illustrative case in a boy, aged 2 years, who recovered, remark that the existence of a pemphigoid or bulbous form of varicella was disputed by Lereboullet and David and their pupil Lebis in 1927, on the ground that the cases hitherto published were either examples of simple pemphigus or cases of pemphigus accidentally associated with varicella. The present case, however, was not an example of epidemic pemphigus or of pemphigus associated with varicella, but was a classical instance of the pemphigoid form of varicella, in which the lesions, which were at first typical of varicella, subsequently assumed a pemphigoid appearance. Moreover, the authors add, *if the case had been one of pemphigus only the patient would undoubtedly have contracted varicella from the other patients* in the ward, where he remained more than a month. Pemphigoid varicella does not appear to be due to secondary infection of the vesicles, since repeated cultures of the serum of the bullae always remained sterile; nor is it caused by an enhanced virulence of the causal organism of varicella, since a pemphigoid varicella may give rise to an ordinary attack, as in the present case, in which the pemphigoid patient infected his brother, who had an ordinary attack of varicella. On the other hand, the authors hold that the supposed epidemics of pemphigoid varicella were probably epidemics of pemphigus.

Surgery.

333. Ligation in Thrombo-Angiitis Obliterans.

G. W. VAN GORDER (*Annals of Surgery*, July, 1929, p. 88) reviews nine cases of thrombo-angiitis obliterans in which high ligation of the main vein of the extremity was employed with good results. This disease of the blood vessels is one in which *arterial occlusion predominates, and in cases of* thrombo-angiitis obliterans the collateral circulation *is the* most promising key to the solution of gangrene prevention. Of the nine cases under review, in five the femoral vein was tied at the apex of Scarpa's triangle, and in the same number of cases the external iliac vein was ligatured just distal to the bifurcation of the common iliac. In two instances obliterated femoral arteries were also cut; in one of these ligation of the left basilic and brachial veins was performed, and in the other the saphenous vein was tied, together with the femoral vein. Three of the first five cases definitely improved; there was cessation of the gangrene, but slight residual pain in one, and failure to relieve symptoms in one. In the five cases with external iliac vein ligations, there was disappearance of pain and cessation of gangrene in three, relief from pain but not from gangrene in one, and no improvement in the fifth until the tip of a gangrenous toe was removed. The two cases in which section of the obliterated femoral artery was performed in addition to vein ligation to relieve pain were failures, as was also the case in which the saphenous vein was tied together with the femoral vessels. Ligation of the basilic and brachial veins was successful in one case. Thus, of nine cases *treated* by high ligation of the vein, there was marked improvement in six, some improvement in two, and no improvement in one; this suggests that if the disease is arrested even temporarily by this method of treatment, the most reasonable explanation is on the basis of an improved collateral circulation. High ligation of the main vein offers a marked resistance to the outflow of blood and an increased venous and capillary pressure, which directs a greater volume of collateral blood from the *normal arteries* of the limb into anastomosing channels that will eventually reach the distant capillary bed. It is concluded that the procedure is of definite value in giving relief from pain, in combating impending or advancing gangrene, and in postponing or obviating high amputation.

334. Bilateral Renal Calculi.

C. BORETTI (*Urol. and Cut. Rev.*, July, 1929, p. 460), who records eighteen personal cases, of which only five were fatal, states that of 300 operations for renal and ureteral lithiasis by Professor Lasio at the Ospedale Maggiore, Milan, 16 per cent. were for bilateral calculi. Such cases are more frequent in men (66.67 per cent.). The earlier the diagnosis the better the prognosis will be, deaths being usually due to an exacerbation of pre-existing uraemic conditions in patients who have come under treatment too late. The diagnosis must be founded on radiography and sometimes pyelography. The functional condition of the kidneys must be determined separately and conjointly by bilateral catheterization, *Ambard's constant, and the phenolsulphonephthalein test.* As bilateral renal surgery must be ultra-conservative, Boretti *recommends pyelolithotomy, by which all kinds of stones* can be extracted from the pelvis and also from the calyces. Where, however, there are several small stones situated in the calyces or in the parenchyma they should be removed by small and, if necessary, multiple incisions, guided by an *exploratory needle.* It is always best to begin with the kidney which functions best. Nephrectomy is an operation which should seldom be performed. Permanent nephrostomy should be preferred when one is not sure about the efficiency of the other kidney.

335. Pyrexia in Malignant Disease.

G. TIZIANELLO (*Il Policlinico*, Sez. Med., September 1st, 1929, p. 452) remarks that the pathogenesis of fever occurring in connexion with new growths has long been the object of discussion, having first been described by Wunderlich; no adequate explanation, however, of it has yet been offered. During the period 1921–26 118 cases of various tumours were treated in the medical department of the Civil Hospital of Venice, their distribution being as follows: digestive system 85; brain 13; larynx, mediastinum, lungs, and pleurae 8; urogenital system 8; glandular and osseous systems 2 each. Of the 118 cases, 43 were accompanied by fever and 75 were always apyrexial. Communication with the exterior does not appear to be an important factor in the development of fever, since the proportion of febrile cases was not higher in the case of the digestive system (36.47 per cent.) or the urogenital system (12.50 per cent.) than in the case of cerebral tumours (12.50 per cent.). This fact, therefore, controverts the view that neoplastic fever is due to secondary infection. Moreover, the tumours are completely shut off, and are capable of themselves of giving rise to fever. Of 17 cases examined histologically by Tizianello, 8 were accompanied by fever; 2 of these were examples of epithelioma, 4 of adenocarcinoma, and 2 of endothelioma. No relation was discovered between the existence of fever and the activity of cell division, necrosis, caseation, or metastasis. Tizianello concludes, therefore, that no connexion can be demonstrated between the presence of fever and the histological type of growth.

336. Congenital Scoliosis.

C. ROEDERER and H. DIJONNEAU (*Paris Méd.*, September 21st, 1929, p. 240) suggest that to limit the term "congenital" to scolioses that are apparent only at birth is somewhat inexact, and that this condition, if late in producing its effects, in none the less always pre-natal. The definition, *postulated* by Roederer and Mouchet in 1922, is accepted; this described congenital scoliosis as a lateral deviation of the spine caused by an embryonic or foetal alteration of the germ, acting on one or more parts of the vertebral column. This elementary alteration terminates, according to its importance and quality, either in a malformation of one bone or of some vertebral elements (the bodies or apophyses), or in a more extensive inequality of development, sometimes involving the whole column. The present authors describe various types of scolioses, those without and those with osseous vertebral anomalies, and spina bifida accompanied by scoliosis; they record cases illustrating each type. The chief characteristics of congenital scoliosis are the following: the paramedian, irreducible, osseous gibbosity; rigidity of the spine; and the absence of all pain, either spontaneous or provoked. A sharp inflexion in the line of the spinous apophyses is often present, and sometimes at the inflexion is felt a deep depression, the spinous foramen of Gourdon, which is characteristic of congenital scoliosis with spina bifida. Radiography is indispensable in diagnosis, and three plates are advisable—namely, full face, in profile, and oblique. The treatment of scolioses is unsatisfactory, since the cause cannot be remedied. The sole *aim must be to* create, above and below the ab[illegible] he curvatures, which will still per[illegible]ly *thoracic* and abdominal organs. F[illegible] watched, and at the slightest menace intervention should be practised. The child is laid on its back in a hypercorrected

plaster cast. When old enough to walk, corsets of reinforced duck for very young infants, or of celluloid for older ones, should be used. Corrective gymnastics should be instituted, and appropriate medical treatment favouring growth (saline baths, lime salts, iodine, etc.) should be given. The authors consider that a congenital scoliosis with perceptible anomalies is less grave than one without these, than a pleuritic or paralytic scoliosis, and even than a juvenile rachitic scoliosis.

337. Congenital Malformations of the Hip.

J. GOURDON (*Gaz. Hebd. des Sci. Méd. de Bordeaux*, September 8th, 1929, p. 566) maintains that the term "congenital luxation of the hip," to designate the affection which characterizes the claudication of cripples, is erroneous. The luxation is not congenital and is produced only when the child commences to stand—that is, when it is about 16 to 20 months old. At birth the only malformations which exist are those which permit femoral displacement by the force imparted from below upwards in the erect position; such are arrested development of the cotyloid cavity, vertical direction of the pelvis, and atrophy and abnormal direction of the upper extremity of the femur. An early diagnosis of these conditions is desirable, before articular dislocation supervenes, when treatment becomes difficult and prolonged and the results are less certain. Gourdon employs the following diagnostic method in every infant who, without any symptom of paralysis, presents an abnormal mobility of the hip which can only be attributed to malformations of the coxo-femoral articulations. The patient is laid on a table and reclines on the sound side. The thigh of the affected side is horizontally flexed and adducted till the knee rests on the table. The leg is then flexed at right angles to the thigh, and, this position being maintained, the lower end of the femur is slowly rotated inwards. If this movement is arrested when the leg is raised not more than 60 degrees above the table the hip is normal; if the elevation exceeds 70 degrees there is articular relaxation; and if it reaches 90 degrees malformations of the cotyloid cavity are present. Internal hyperrotation is an efficient treatment for restoring the cotyloid cavity to its normal state; it is sufficient to place the thigh in abduction at right angles for a quarter of an hour three times daily. The child should be allowed to assume the upright position only after four months of this treatment. Gourdon reports excellent results from this method in all cases that he has followed.

338. Vesical Calculus and Enlarged Prostate.

G. MILLUL (*Il Policlinico*, Sez. Chir., July 15th, 1929, p. 365) records fifteen cases of vesical calculi in patients suffering from enlarged prostate and retention. He remarks that it is not always easy to diagnose the presence of calculi from symptoms alone, though certain symptoms are suggestive of their presence. In the prostatic patient who has calculi but no great amount of residual urine, pain on micturition comes on towards the commencement of micturition rather than at the end; it is aggravated when the contractions of the bladder are frequently repeated, or when the bladder is partly emptied and the stone irritates the bladder wall. Haematuria of the vesical type, brought on by movement and ceasing during repose, is suggestive. The safest way to establish the diagnosis is to radiograph the bladder. In all the author's cases the calculus was of local origin, and there was no evidence of any renal stone. Catheterization, lavage, infection, and retention of urine are each likely to originate a calculus.

339. Senile Gangrene.

W. SAMPSON HANDLEY (*Journ. Coll. Surg. Australasia*, July, 1929, p. 38) describes his experience with periarterial alcohol injections in the treatment of threatened senile gangrene as compared with arterial sympathectomy. In the latter procedure a certain length of the outer coat of the artery is stripped off, thus interrupting the sympathetic nerves running thereon, and producing a vaso-dilator action on the parts below. A local contraction of the artery occurs, so that a low circulation, lasting for a time up to fifteen hours, precedes the onset of the vaso-dilator symptoms, which eventually supervene for three or four weeks. Such an initial vaso-constriction may be very dangerous in threatened gangrene, and the period of subsequent vaso-dilatation is too short to permit separation of the toes or of a portion of the foot. In periarterial alcohol injection there is no initial period of diminished circulation, vaso-dilatation being produced at once without any local contraction of the artery at the site of injection, and without any temporary aggravation of the condition. The method is useless in thrombo-angiitis obliterans, and in cases in which the temperature of the gangrenous foot is higher than that of the sound foot; in Raynaud's disease, however, and in infantile paralysis with capillary congestion, it may avert a more serious procedure and produce some degree of improvement. The author adds that in cases with signs of threatened gangrene the procedure should be employed before actual gangrene has occurred, or while it is still confined to a small area.

340. Acute Glanders.

J. W. ROELOFFS (*Nederl. Tijdschr. v. Geneesk.*, July 13th, 1929, p. 3272), who records an illustrative case of acute glanders, illustrates the rarity of both the acute and chronic forms of the disease by the fact that the last instance in Holland was recorded in 1913 by Van der Valk and School, who published a case of chronic glanders. The present patient was a laboratory attendant, aged 33, in whom the disease developed after an incubation period of a few days, with symptoms of septicaemia. At the end of a fortnight he developed a characteristic rhinitis with a sanious discharge, typical lesions in the skin and mucous membranes in the form of small bluish nodules which rapidly broke down, and typical foci in the lungs, as well as non-specific infiltration. Treatment consisting of intravenous injections of 5 c.cm. of 2 per cent. solution of trypaflavine was of no avail, and the disease ended fatally in nineteen days. Glanders bacilli were found in the blood, pustules, and throat mucus.

Therapeutics.

341. Therapeutic Vasotrophic Shock in Asthma.

ACCORDING to G. BOUCHÉ (*Le Scalpel*, August 17th, 1929, p. 889) the typical lesions of the respiratory tract found in asthma should not be considered causal, since they are frequently present in non-asthmatic cases such as bronchial and nasal catarrh or emphysema. With regard to the physiological pathology, he rejects the hypotheses of direct vagus irritation (although admittedly this is found in rare cases associated with wounds) and of excessive carbonaemia, and he holds that the immediate cause is vasotrophic shock associated with parasympathetic irritation, in the second stage of which a rise of the blood pressure occurs. The agents of shock are innumerable, and any one may precipitate the irritation. Individual variation may determine lesions of this irritation to one particular system; for example, damage of the lungs by gaseous irritants may lead to its manifestation in bronchial asthma. The shock is not necessarily anaphylactic; Bouché admits that occasionally sensitiveness to one particular protein may cause asthma, but he does not practise routine search for any one cause. His method of treatment is to inject substances producing shock, in amounts giving a minimum of local and general reaction; such substances are the serums, crotalin, and vaccines, the stock varieties being found as efficacious as the autogenous. He remarks that asthmatic patients usually react violently; it is therefore wise to use serums diluted 1 in 10 in doses of about 1 c.cm. Some patients are hypersensitive to serums, and crotalin or vaccines are preferable; patients with tuberculous lesions are particularly sensitive to serums. Doses sufficient to precipitate crises should be avoided, and they should be diminished also during periods of respiratory excitation. Treatment should be continued for eighteen months to two years after the subsidence of attacks. Bouché recognizes two main varieties of tractable cases. In hay fever the treatment should be begun two months before the "season" and be continued to its end; in this class he has had only one failure in twelve cases. As regards the nervous type of asthma, the author states that he has no experience of treating patients with gross pleural lesions or continual bronchitis, but he does not exclude from treatment those with small inactive apical lesions. He defines three stages of treatment as follows. (1) In the course of the first six or seven injections the patient's degree of sensibility is determined and an appropriate dosage evolved; sometimes improvement is noticed from the first dose. (2) The reactions become fixed or gradually less. Attacks become less frequent and more amenable to palliation; the length of this period is variable. (3) The crises disappear, but the treatment should be continued for a period ranging from some months to two years. Of 17 cases treated by the author he claims twelve complete cures of varying duration and three temporary ameliorations; he admits two complete failures in patients who could not tolerate the initial reactions. He thinks that the treatment of patients with latent tuberculosis is too risky to be worth attempting. With regard to the antigen employed, he suggests that it is always worth while to vary the nature of the injection, but that the success of any substance is almost always empirical, prolonged search for a specific one being waste of time. In associated "shock lesions," such as urticaria with asthma, it is noteworthy that one lesion may

disappear before the other. There appears to be a "refractory period" after asthmatic crises during which attacks cannot occur. Bonché considers that in cases with severe attacks at long intervals the "refractory period" mechanism is well developed, and that such cases are favourable for shock treatment; conversely, in patients with frequent slight attacks the condition is more intractable. He advances a theory that non-specific immunization is due to excitation of all the body cells, and especially those of the parasympathetic nervous system, with the resulting production of receptors capable of fixing antigens, of whatever nature, which previously precipitated parasympathetic irritation.

342. Sodium Cacodylate in Malaria.

RENÉE ULLMANN-APOSTOLON and G. APOSTOLON (*Presse Méd.*, August 31st, 1929, p. 1137) have been treating old-standing cases of malaria in Macedonia during the past ten years with large doses of sodium cacodylate; the patients had enlargement of the spleen and liver, pronounced anaemia, and some jaundice. Quinine even in large doses failed to effect a cure, although the attacks were controlled. Large intravenous injections of neosalvarsan were first tried with unsatisfactory results, so the authors turned to the procedure advocated by Carnot and Ravaut. Their routine treatment consisted of a series of graded courses. On the first day they gave an intravenous injection of 0.5 gram sodium cacodylate; 1 mg. of strychnine sulphate was injected subcutaneously; and 1.5 grams of quinine was given by the mouth. On the second day the doses were: 1 gram of sodium cacodylate; 2 mg. of strychnine sulphate; and 1.5 grams of quinine. During the subsequent days the same doses were given except that the strychnine was increased to 3, 4, or even 5 mg. according to the susceptibility of the patient. If after seven days all went well the cacodylate was increased to 1.5 grams. In each course 15 to 18 grams in all of sodium cacodylate were given, and at the end of the first course the treatment was discontinued for ten days. A second identical course was followed by a twenty-day period; a third by a month; and after the fourth course further treatment was rarely necessary. The patient's condition began to improve soon after the beginning of the treatment; the anaemia disappeared, the spleen and liver decreased, and repeated microscopic examinations of the blood for the parasites proved negative. The authors assert that there were no other drawbacks to this heroic treatment except that in 3 to 5 per cent. of the cases a generalized eruption appeared, with puffing up of the face and swelling in the parotid region. These manifestations soon disappeared on a light milk diet without any particular medical treatment. In 10 to 15 per cent. a slight diarrhoea occurred, but was easily controlled by laudanum. Children were also similarly treated, but the dose of cacodylate was reduced to 0.1 gram for each year of age up to 10, and the results were similarly successful. Pregnant women were also treated with the ordinary doses and no ill effects were produced, even during the last months of pregnancy.

343. The Action of Digitalis on the Heart.

W. D. REID (*Journ. Amer. Med. Assoc.*, June 22nd, 1929, p. 2090) refers to the well-known effect of digitalis upon the conducting system of the heart. This effect is manifested chiefly by the production of such arrhythmias as extrasystoles, coupled beats, ventricular escape, auricular and ventricular fibrillation, and paroxysmal tachycardia. Experimental work upon cats showed that therapeutic effects were produced by 25 to 50 per cent. of the minimal lethal dose: 50 per cent. doses caused prolongation of the PR interval, while 70 per cent. of the minimal lethal dose was necessary to cause coupled rhythm and ventricular escape. The author has shown that these results are applicable to man, and he has been unable to find in the literature any convincing record of patients dying from heart-block resulting from digitalis medication. A few cases are recorded in which heart-block existed over many years, causing no reduction in effort tolerance. In them the myocardial lesion must have been confined to the conducting system, and there [illegible] the great majority of heart-block case[s] [illegible] n conduction is but a part of widespre[ad] [illegible]. Digitalis produces an effect comparable to the former group, and therefore should cause no embarrassment to the cardio-vascular system. Heart-block in general has been identified with the second group, in which the prognosis is serious, and therefore the possible dangers of digitalis block have been over-estimated. The author [illegible] that digitalis produces its beneficial [effects] [illegible] inducing a degree of block which pro[duces] [illegible] m receiving an excessive number of [beats] [illegible] urges its administration until either good results are obtained or toxic symptoms produced.

344. Treatment of Tapeworm Infestation.

S. MARGULIS (*Münch. med. Woch.*, September 6th, 1929, p. 1510) has treated more than forty adults and children infected with tapeworm by administering an emulsion of the extract of *Filix mas* and infusion of senna in gum arabic through a duodenal tube; he has obtained entirely satisfactory results. The patients receive two preliminary doses of sodium sulphate at 5 and 8 p.m. on the previous day; a water enema is given next morning, and this is followed by the passage of the duodenal tube and the administration of the emulsion. Margulis found that the advantages of this method were the avoidance of nausea and vomiting; smaller doses were as a rule required, which was particularly valuable in children. He was by this means able to obtain the evacuation of the head of the tapeworm in several cases which had hitherto proved refractory; in one case as many as four tapeworms were found. The doses of *Filix mas* varied from 6 c.cm. for an adult to 2 c.cm. for a child 5½ years old.

Ophthalmology.

345. Ocular Anaphylaxis.

RECALLING that in 1903 Uhlenhuth showed that animals could be sensitized and immunized with lens protein, and that this hypersensitivity was tissue specific and not species specific, A. N. LEMOINE (*Arch. of Ophthalmol.*, June, 1929, p. 706) reviews the literature on ocular anaphylaxis. The conclusion reached is that allergies play a definite and important rôle in many ophthalmic clinical entities, but that in most cases allergy is not the underlying cause, but merely a manifestation of a disturbed endocrine balance, with a resulting disturbance of the metabolic and biochemical function. Cases of vernal catarrh are reported in which cure was obtained by the administration of thyroid and parathyroid extracts with calcium. A case of vernal conjunctivitis following removal of the ovaries cleared up after ovarian and thyroid extracts had been given. Similar cures are reported in phlyctenular keratitis, dendritic ulcers, corneal herpes, and other ophthalmic conditions. Lemoine asserts that the great majority of patients in whom these allergic phenomena develop have endocrine disturbances, and that the treatment for ocular anaphylaxis is the correction of these disturbances. The antigen causing the allergy should be identified and removed from the patient if possible. If this cannot be done the patient should be immunized to the antigen in question, and apparently this immunization must be repeated about every two years. Many patients can be cured of these allergic phenomena by glandular therapy, most commonly of the thyroid, parathyroid, and gonads.

346. Amaurotic Family Idiocy in Japanese Families.

F. C. CORDES and W. D. HORNER (*Amer. Journ. Ophthalmol.*, July, 1929, p. 558) record two cases of this disease occurring in Japanese families. Amaurotic family idiocy was at one time thought to occur in Jewish families only. Latterly, however, several cases in non-Jewish families have been reported. Up to the present no cases have been noted as occurring in Japanese families. Of the present two cases one was characteristic of the condition in every way. The other was not quite so typical in that the symptoms developed somewhat later in life, and the eye symptoms antedated the other changes considerably. In each of these two cases the parents were first cousins. Consanguinity is very frequent in this disease. With regard to sex, the two cases reported were females; of reported cases, it would appear that in the Jewish families the sex incidence is approximately equal, whereas in the non-Jewish families the females are most often affected.

347. Treatment of Herpes Zoster Ophthalmicus.

J. S. FRIEDENWALD (*Bull. Johns Hopkins Hospital*, August, 1929, p. 103) reports an unexpectedly favourable result in an unusually severe instance of ophthalmic herpes zoster in which he made use of convalescent serum. In a woman, aged 47, a lesion resembling simple herpes developed on the left cheek; the left eye subsequently became inflamed, and minute infiltrations were noted in the cornea. Later there was diffuse hyperaemia throughout the region of the ophthalmic branch of the left trigeminal nerve, with many minute skin vesicles in this area. Typical zona lesions subsequently spread from the tip of the nose to the vertex of the scalp. They were also present on the nasal mucous membrane and the palpebral conjunctiva, and were associated with corneal infiltrations of increasing size, iritis of the left eye, great oedema of the lids, severe pain, and pyrexia. Five days after the onset of the cutaneous lesions, and eleven days after the start of the neuralgic pain, the patient received an intramuscular injection of 8.5 c.cm. of blood serum from

another patient who, six weeks before, had recovered from a severe attack of perineal zoster. Five hours after the injection a marked freedom from pain was reported; by the next morning the lid oedema had much decreased, and the skin rash began to subside rapidly. The iritis, however, was very stubborn, and its treatment was complicated later by the development of a local allergy, first to atropine and then to all other mydriatics. Two months later the vision of the left eye was 6/12, but in another two months it had improved to 6/6. Friedenwald remarks that cases of ophthalmic herpes zoster with such extensive lesions usually end in complete loss of vision from the corneal involvement, and he considers, therefore, that the favourable sequel in his case could hardly have been anticipated. Another unusual feature was the iritis, which is not commonly found in these cases.

Obstetrics and Gynaecology.

348. The Morphology of Normal Menstrual Blood.

AFTER citing the work of von der Leyen, Rotter, and others on the morphology of menstrual blood, S. H. GEIST (*Surg., Gynecol. and Obstet.*, August, 1929, p. 145) records the results of his own investigations, in which he found that menstrual blood contains a definite number of elements which are so characteristic and stable as to enable its differentiation with certainty from blood of other types of genital bleeding; he believes that this difference may afford a valuable diagnostic aid in pelvic diseases accompanied by haemorrhage. Studies were made of 100 specimens, some of which were taken during the whole menstrual period, others only on certain days. The constituents particularly studied were the vaginal and uterine epithelium and the mononuclear and polynuclear leucocytes. To obtain the material a glass tube was placed in the vagina, just within the introitus, and was held in place by adhesive tape. The uterine epithelium appeared as small strips of columnar epithelium with only a few cells, or of long strands with many cells. It occurred also as small clumps of glands, in some instances of only one gland. In other specimens the epithelial tissue formed large fragments with tortuous glands and surrounding stroma, while in several instances large masses, similar to those expelled in membranous dysmenorrhoea, were found. Clumps of stroma cells were observed, independently of the epithelium, as small groups of darkly stained oval, round, or polygonal cells, ranging in number from five to twenty. The stroma did not show the same extent of necrosis as the epithelium, though in both the viable far exceeded the degenerative tissue. The presence of these fragments is considered extremely characteristic and constant, and to be sufficient to warrant a diagnosis of menstrual blood. Both the stroma and epithelium appear on the first day, increase progressively up to the third day, maintain a maximum desquamation for two days, then diminish on the fourth and fifth days. Another striking finding was the presence of desquamated vaginal epithelium as isolated cells or in plaques. The isolated cells were short flat spindles with a small round central nucleus. Three types of plaques were found: plaques of squamous epithelium, varying from three to one hundred or more cells, and from three to twenty layers; plaques of large spheroidal or polygonal cells; and strands of cells, one or more layers in thickness, crowded, non-nucleated, and dark. The number of polynuclear leucocytes varied greatly, and in some instances was so great as to suggest pus. The number found in the discharge in the vagina was always greater than that in the blood from the cervix. Apparently pelvic infection did not always cause a leucocytic increase in the vaginal blood, and the cause of this variation in number is unknown.

349. Sacral Nerve-block in Obstetrics.

C. H. KNAUER (*Anesthesia and Analgesia*, July–August, 1929, p. 243) considers that the production of a sensory nerve-block, thus preventing pain impulses from reaching the cerebrum, is the ideal form of obstetrical anaesthesia. The objections to gas and other forms of anaesthesia are contrasted with the

and its overlying structures is briefly recalled. The dural sac ends at the third sacral segment; the sacral canal below this contains the trunks which form the sciatic and pudic nerves, and it is these trunks that are anaesthetized in this variety of nerve-block. Knauer uses 33 c.cm. of a solution of 2 per cent. apothesin or procaine (the latter is said to be the more desirable) and 0.5 per cent. of quinine-urea hydrochloride with five drops of a 1 in 1,000 adrenaline chloride solution. The quinine salt acts as an oxytoxic on the uterine muscle and increases its action. By using 30 c.cm. of a solution containing 10 grains of procaine, 2.7 grains of the quinine salt, and 5 drops of the adrenaline solution, anaesthesia of the sacral area is complete in from fifteen to forty-five minutes, and lasts from twelve to forty-eight hours. Not uncommonly a few toxic symptoms occur, such as pallor, accelerated pulse, and nausea, but these are never of an alarming degree. This technique produces no untoward effects on the mother or child other than those mentioned. The injection may be made any time after there is two or three fingerbreadths' dilatation of the cervix, or after the head has fully engaged, and the character of the pain is such as to demand relief. Two brief summaries of typical case reports are given.

350. Adenocarcinoma of the Uterus.

J. V. MEIGS (*New England Journ. Med.*, July 25th, 1929, p. 155) reports the results of investigations in 206 cases of adenocarcinoma of the fundus of the uterus in which 25 (12.1 per cent.) showed vaginal metastases. All the patients had passed the menopause, and the symptoms of a possible extension to the vagina were discharge and bleeding recommencing after hysterectomy or radium treatment. When the metastatic nodule in the vagina was present and ulcerated at the original operation, there was no intermission of the bleeding and discharge. Meigs remarks that it is important to bear in mind the possibility of such metastases; a vaginal carcinoma should not be regarded as the primary condition until the uterus has been investigated with a view to detecting adenocarcinoma of the fundus; after hysterectomy or radium treatment the necessity for a careful vaginal examination is obvious. The lymphatics, or possibly the veins, are the most probable channels by which metastases occur; direct implantation is less likely. Treatment consisted either of total hysterectomy followed by radium application to the vaginal metastases, or radium was used both in the uterus and in the vaginal growth; the first procedure was preferred when the metastases appeared to be treatable and the uterine tumour operable, while the latter should be employed if either the metastasis or tumour is inoperable or untreatable. The best treatment for the vaginal metastases appears to be infiltration with gold or glass seeds and surface application with about 2,500 millicurie hours of lead-screened radiation.

351. The Haemostatic Action of Calcium during Labour and the Puerperium.

SINCE it has been found that the blood calcium is diminished from the normal 10.20 mg. per cent. to 9.40 mg. per cent. at the end of pregnancy, S. SZENTEH (*Zentralbl. f. Gynäk.*, July 20th, 1929, p. 1828) conducted a series of tests in order to ascertain what effect the administration of calcium had on the haemorrhage following parturition. Though the blood calcium was low in all the cases examined, the bleeding time and coagulation time only exceeded the normal in five out of forty cases, in all of which the loss of blood immediately after delivery exceeded 300 c.cm. Calcium was administered to all these patients by injecting 0.5 c.cm. of a 10 per cent. preparation of calcium chloride into an arm vein very slowly, the piston of the syringe being withdrawn several times during the course of the injection in order to mix blood and calcium solution in the syringe and thus prevent unpleasant secondary effects. During the injection the pulse rate fell, but reverted to its previous rate in five or six minutes; the *uterus contracted and the haemorrhage was satisfactorily controlled.* In a few patients in whom the uterus was very flabby the calcium preparation was mixed with pituitary extract; the resultant effect on this organ was found to be much more marked than when pituitary extract alone was injected. The effect produced by the calcium injections is ascribed by Szenteh to increased thrombosis in the uterine vessels and to increased contraction of the organ, the latter being probably partly due to stimulation of the sympathetic innervation of the uterus, and partly to increased sensitization of the uterus to circulating pituitary hormone. The fall in blood pressure recorded in a number of cases after the injection also has a beneficial effect in arresting haemorrhage. During the puerperium calcium was injected intravenously into sixty patients in whom the lochia remained red after the fourth day and the uterus was not involuting normally; seven of these patients received more than one injection. The results were satisfactory, though no definite effect was observed when 6 grams of calcium lactate were administered orally as a routine to fifty puerperal women, and the duration of red lochia and rate of involution of the uterus in these were compared with that of fifty controls who received no calcium. Though no case of venous thrombosis occurred in Szenteh's series after the injection of calcium, he advises that, in view of this risk, the use of intravenous calcium should be restricted during labour (1) to patients with mild atonic conditions of the [illegible] hon pituitary extr[illegible] (2) to patients with [illegible] calcium injection [illegible] itary extract;

and (3) in conditions such as thrombopenia, haemorrhagic diathesis, and certain infections associated with diminished coagulability of the blood. During the puerperium intravenous calcium injections should be used if the lochia remain red after the fourth day, provided, of course, that there has been no retention of the placenta or membranes.

352. Puerperal Scarlet Fever.

ACCORDING to P. BAIZE and M. MAYER (*Presse Méd.*, August 3rd, 1929, p. 1007), who record six illustrative cases in women aged from 17 to 39, all but one of whom were primiparae, the etiological features of puerperal scarlet fever are as follows. Two-thirds of the cases occur in primiparae. In most cases the source of contagion cannot be discovered. In the great majority of the cases the disease sets in on the third to fifth day after delivery. The symptoms differ but slightly from those of ordinary scarlet fever. The gravity varies in different epidemics. None of the authors' cases was fatal. Generally speaking, the prognosis is likely to be grave when the incubation period (the interval between delivery and the onset of symptoms) is short. As regards the pathogenesis, the authors hold that two groups of puerperal scarlet fever may be distinguished. The first consists of cases of ordinary scarlet fever which has developed as a mere coincidence in the puerperium, while in the second group, which is much larger, the attack has been the result of the endometritis, which is usually slight. These two groups of scarlet fever must be distinguished from puerperal scarlatiniform erythema by the Schultz-Charlton reaction.

Pathology.

353. Isoagglutination and Paternity.

E. WOLF (*Acta Med. Scand.*, June 12th, 1929, p. 54) has determined the blood groups of 503 persons—162 women, 172 men, and 169 children—collected from all parts of Sweden. The distribution of the groups was 180 (35.6 per cent.) O; 232 (46.1 per cent.) A; 60 (11.9 per cent.) B; and 31 (6.2 per cent.) AB, figures which agree very nearly with those of other observers. Of 166 children, 63 (41 per cent.) belonged to a different group from the mother; in 39 (23.5 per cent.) children there were A or B receptors which were absent in the mothers. Of the 63 children of 61 mothers of group O no child belonged to AB group; of 59 children of group O no mothers belonged to group AB—that is to say, neither combination AB mother +O child, nor O mother + AB child, occurred in the material examined. The object of the investigation was the practical application of isoagglutination groups in cases of disputed paternity, whereby exclusion of parentage would be considered only in those cases where the child's agglutinogen was absent from the mother and also from the alleged father. In a sample of 152 cases a possible exclusion of the father occurred in 9 cases (6 per cent.). Among 23 children of 22 cases where both mother and supposed father belonged to group O, there were 2 group A children and 1 group B child. Among 36 children of 35 cases where both mother and father belonged to group A there were 2 group B children and 1 group AB child. Among 52 children of 51 cases where mother or father belonged to A or O group respectively there were 2 AB children and 1 B child. When the mother and father are both AB and the child O, the father must be definitely excluded.

354. Influence of Iron on the Pigmentation of Acid-fast Bacteria.

G. B. REED and CHRISTINE E. RICE (*Journ. Bact.*, June, 1929, p. 407) find that, when acid-fast bacilli are grown in a medium containing iron, pigment of a yellow, brown, or pink variety is formed very much more readily than in a similar medium to which iron salts have not been added. The particular medium employed consisted of a beef-infusion agar containing glycerol; to this was added 0.2 gram of ferric citrate per litre. The reaction was adjusted to *p*H 7.4; at this reaction the citrate maintains the iron in solution, but if the *p*H passes above 8.0, even in the presence of the citrate, the iron is precipitated. Several strains of acid-fast bacilli were tested on this medium, including avian, human, and bovine types of tubercle bacilli, certain of the saprophytic acid-fast bacilli, and four strains of the leprosy bacillus. The results were very striking: in all cases pigment, varying in depth, was formed on this medium, whereas on the medium to which no iron had been added many strains gave no pigment at all. This effect of iron salts appears to be mainly confined to the acid-fast bacilli; experiments made with a number of other bacteria, such as staphylococci, pseudomonas, chromo-

ing group, showed
the same amount
n the special iron-

medium.

355. Lipoids in the Uterine Decidual Cells.

S. MARTINES (*Ann. di Ostet. e Ginecol.*, June 30th, 1929, p. 711) reports a study of 28 cases in which the uterus was studied from the point of view of its fat content, and particularly of lipoids. At different periods of pregnancy from the second month to full term longitudinal sections of the uterus were examined, one at the insertion of the placenta and one on the opposite side of the uterus. The sections were fixed in formalin and stained with osmic acid, Sudan III, and Ciaccio I. The author concludes that fats and lipoids are part of the normal contents of the decidual cells throughout pregnancy. The fats of the chorionic villi he considers to be an indication of their lipolytic and lipogenetic activities, which give to the foetus necessary elements of life. Fats and lipoids were found to be present in greater quantity during the first half of pregnancy than during the second half. The author deduces that these fatty substances are essentially the expression of endocrine activity in the decidual cells and not a product of degeneration. This activity probably has a direct bearing on the uterine mucosa, or on the muscles and vessels. During the second half of gestation, and especially near its termination, this endocrine activity ceases; the decidual cells go through their cycle of evolution, and manifest degenerative changes, which are not only appreciable under the microscope, but can be detected by the naked eye.

356. Estimation of the Degree of Immunity to Measles.

WITH a view to obtaining a definite indication of susceptibility to measles, W. L. BRADFORD (*Journ. Infect. Dis.*, May, 1929, p. 378) tested 96 children intradermally with the broth filtrate of the Tunnicliff coccus, with the following results. It has been suggested that some specific skin reaction might exist. Of 43 who gave a history of measles, 2 were positive and 41 negative; while of 53 who had not had measles, 10 were positive and 43 negative. In another series of 109 children tested with the Tunnicliff antigen, of 69 who had had measles 17 were positive and 52 negative, while of 40 with a negative history of measles 12 were positive and 28 negative. Similar results were obtained with the filtrates and with the antigens produced by *Streptococcus morbillosus*, by the Duval coccus, and by a stock culture of *Streptococcus viridans*. Reactions were more frequently negative in young infants and during the immediate convalescence from measles. Although the test was negative, as a rule, in persons who had had the disease, it was also generally negative in those who had never had measles. Bradford concludes that cutaneous reactions to the toxic filtrates and antigens of the green-producing cocci mentioned do not provide any basis for distinguishing patients immune to measles from those who are susceptible.

357. Malarial Parasites in Bone Marrow.

G. SORGE (*Rif. Med.*, June 29th, 1929, p. 872) questions the common statement that the bone marrow is a refuge for malarial parasites when they are not observed in the peripheral blood. In nine cases of aestivo-autumnal infection the author examined smears of bone marrow (*stained* by the Romanowski-Giemsa process) obtained from the sternum by puncture under local anaesthesia. In five cases parasites were not observed in the blood at the time of the sternal puncture, and of these in every case after prolonged careful search the marrow appeared free from parasites; three of these patients subsequently suffered relapses. In the other four instances parasites were seen in the peripheral blood. In two the number of parasites was remarkable—three to four to each microscopic field—but in the sternal bone marrow they were only sparsely present; in the other two cases in which the parasites were fewer in the blood—one to every four fields—the examination of the bone marrow was in both cases negative. The author concludes that the bone marrow *is not serviceable for diagnostic purposes* in cases of suspected malarial infection where the blood examination is negative. There is no correspondence between the numbers of parasites in the blood and in the bone marrow, being much less in the latter; this applies not only to sporulating forms, but also to the sexual stages. The bone marrow is thus not a refuge for malarial parasites during the period of latent infection.

358. Saprophytism of Ducrey's Bacillus.

L. CACIOPPO (*Rev. Sanit. Sicil.*, August 1st, 1929, p. 988), who records an illustrative case and quotes similar examples recorded by Pautrier, Roderer, Ulmo, and Lépinay, maintains that Ducrey's bacillus, the organism of chancroid, may live as a saprophyte on otherwise healthy mucous membranes, and that women who have no venereal ulcers may be the source of contagion with soft chancres. The author remarks that this fact is of considerable medico-legal importance, and shows the necessity of repeated microscopical and cultural examinations in cases of this kind.

Permanence of "Vita" Glass
the only British Window Glass that admits the ultra-violet rays

GUARANTEE

WE, the "Vita" Glass Marketing Board, HEREBY DECLARE that the power of "Vita" Glass to transmit the ultra-violet rays to the furthest limits of the sun's spectrum is absolutely permanent. Every pane of "Vita" Glass is sold under guarantee of permanent transmission of the ultra-violet rays.

For the "Vita" Glass Marketing Board,

(Signed) H. M. Byrne

Director.

This statement is published as a direct denial of the current rumour that "Vita" Glass, after exposure to light, loses its special properties and becomes like ordinary glass. There is not an atom of truth in this rumour, which has gained credence by the fact that "Vita" Glass, in common with all other glasses, undergoes some change when exposed to light and then becomes stable.

Both before and after stabilisation "Vita" Glass transmits the ultra-violet rays to the furthest limit of the sun's spectrum.

The amount of the deterioration has been greatly exaggerated owing to the artificial method in which the so-called solarisation has been effected in laboratories. Recent research shows that glass stabilised by these *artificial* methods regains a substantial part of its lost transmission on subsequent exposure to sunlight.

The results of these tests are available to all interested persons, and those who have any doubt of the permanent value of "Vita" Glass to health, are urged to write at once for other evidence to the "Vita" Glass Marketing Board.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

THE LINING—— a big feature in Suit Service.

THE main object of sports clothes is the utmost freedom of movement. A suit with a harsh unyielding lining is far from being comfortable in wear. Many linings feel smooth and look well at first, but the conditions of golf and the several other forms of sport show that the surface is only surface. Following a few strenuous days' wear, the Lining may even split. With "COURTINE" LININGS —woven by COURTAULDS—there is no danger. Their smoothness and clear colour outlast many seasons' hard use. Ask your Tailor to use

"Courtine (REGISTERED) LINING

The name is on the selvedge.

Convalescent patients should wear Wolsey!

IN convalescence it is essential that patients should guard themselves against a relapse caused by sudden lowering of temperature.

To avoid this danger, advise your patients to wear Wolsey Pure Wool Underwear because it keeps the body at even temperature and gives utmost health protection and comfort.

Don't be misled— Look for the Head

Wolsey Garments can be obtained from all good high class Drapers and Outfitters.

PROVED MORE EFFICIENT THAN NICKEL-PLATED INSTRUMENTS

NOT once, but many times, Doniger Krome-Plate Instruments have proved their superiority in practical tests carried out in some of the most important hospitals and clinics of America.

The reason for this superiority is not far to seek. Doniger Instruments are made from high carbon steel of fine quality. They are fashioned by master craftsmen and polished to the highest degree of smoothness. They are then nickel-plated, and finally given a heavy plating of pure chromium. This treatment makes Doniger Instruments—

(a) much harder and stronger;
(b) rust-resisting;
(c) last five times as long as nickel;
(d) retain their original brightness.

These advantages make the use of Doniger Instruments a very real economy, especially so in conjunction with the fact that Doniger Instruments cost only a fraction more than nickel-plated Instruments.

You are invited to apply to your usual Supply House for full particulars and prices.

Doniger Instruments are not supplied direct to the Profession.

"EUMENTHOL JUJUBES" (HUDSON)

Made in Australia.

HARMFUL THROAT TABLETS. Throat Tablets and Lozenges containing Formalin (Formaldehyde) are harmful. Wiley, of the United States, investigated the effects of small doses of Formalin (Formaldehyde) given with milk, on 12 men during 15 days. Burning in the throat, itching rash, and loss of body weight were observed.—*Vide* Martindale. All countries which have made legal enactments and laws regarding the purity of its food supply have prohibited the addition of Formaldehyde (Formalin) as a preservative of food. HUDSON'S EUMENTHOL JUJUBES contain no Formalin, Cocaine, or other harmful or poisonous drug. Sold everywhere.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: The Most Hon. the Marquess of Exeter, C.M.G., A.D.C.

Medical Superintendent: Daniel F. Rambaut, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facilitiy for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentiy, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

HAYDOCK LODGE,

NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and out-door recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

For terms, etc., apply to the Medical Superintendent.

Royal College of Surgeons of England.

ANNUAL MEETING OF FELLOWS AND MEMBERS.

Notice is hereby given that it is proposed to hold a MEETING OF FELLOWS AND MEMBERS at the College in Lincoln's Inn Fields on Thursday, NOVEMBER 21st, 1929, at 3 o'clock p.m., and that a Report from the Council will be laid before the Meeting. Fellows and Members can obtain copies of the Report on application to the Secretary, and can, if they so desire, have their names placed on the list of those to whom the Report is sent annually.

Motions to be brought forward at the Meeting must be signed by the mover, or by the mover and other Fellows and Members, and must be received by the Secretary not later than November 11th.

Copies of the Agenda will be issued on or after November 14th to any Fellow or Member who may apply for one.

S. FORREST COWELL, Secretary.

October 16th, 1929.

The University of Adelaide.

ELDER PROFESSOR OF ANATOMY AND HISTOLOGY.

Applications are invited for the Elder Professorship of Anatomy and Histology in the University of Adelaide, South Australia.

The Professor will be required to offer courses of lectures and practical work in Anatomy and Histology suitable for students in Medicine and in Dentistry, together with advanced courses suitable for Honours students in Science.

The services of a full-time lecturer are provided and also a technician.

Salary £1,100 per annum.

Applications, with testimonials, statement of age, academic qualifications, experience, and copies of publications, should reach the Registrar, the University of Adelaide, South Australia, not later than January 1st, 1930. Candidates must state the earliest date after March 1st at which they can take up their duties.

Further information may be obtained from:

(a) The Agent-General for South Australia, Australia House, Strand, London.

(b) Any University in Australia or New Zealand.

F. W. EARDLEY, Registrar.

South Australian Government.

The Agent-General for South Australia has been instructed by the South Australian Government to secure the services of TWELVE JUNIOR MEDICAL GRADUATES (Women Graduates will be eligible) for service at the ADELAIDE HOSPITAL.

The terms of engagement will be for one year, commencing February, 1930, with a salary of £100 per annum, in addition to apartments, rations, fuel, and light, such salary to commence from time of taking up duties.

Selected applicants will be nominated by the Hospital Board, and the cost of single passage to Adelaide will be borne by the Government.

Applications for the above appointments will be received until October 31st, at the Office of the Agent-General for South Australia, Room 216, Australia House, Strand, London, W.C.2.

University of Leeds.

CANCER RESEARCH FELLOWSHIP.

The Senate of the University will shortly proceed to the election of a Cancer Research Fellow in the Department of Experimental Pathology and Cancer Research. The value of the Fellowship will be £500 per annum. Candidates must possess a registrable medical qualification. The conditions of appointment may be obtained from the Clerk to the Senate.

Preliminary Examinations.

The COLLEGE OF PRECEPTORS holds Preliminary Examinations for Medical and Dental Students in London and at Provincial Centres in March, June, September, and December. For Regulations, apply to the Secretary, College of Preceptors, Bloomsbury Square, London, W.C.1.

Invalid and Crippled Children's Hospital.

Balaam Street, Plaistow, E.13.

Applications are invited for the post of HONORARY SURGEON to the Ear, Nose, and Throat Department (8 beds and out-patients), Friday afternoons.

Applications, with copies of testimonials, should be sent to the Secretary not later than Friday, November 1st.

B. I. HOWARD, Secretary.

ROYAL NAVAL DENTAL SERVICE.

The Admiralty is prepared to receive applications from qualified Dental Surgeons for entry into the Royal Navy as DENTAL OFFICERS.

Two vacancies are to be filled. Candidates must be below 28 years of age on December 31st, 1929 (unless granted an allowance for age, not exceeding six months, in respect of a period served in a recognized Civil Hospital appointment), and must be registered under the Dentists Act as qualified to practise as Dental Surgeons in Great Britain and Ireland. They will be required to appear before a Selection Committee and to pass a medical examination by a Board of Naval Medical Officers as to their physical fitness for entry.

The Regulations for entry and the forms to be filled up by candidates can be obtained on application to the Medical Director-General of the Navy, Queen Anne's Chambers, Tothill Street, London, S.W.1.

The form of application, accompanied by the necessary documents, must reach the Medical Director-General not later than November 18th.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

BAGULEY SANATORIUM. (333 Beds.)

APPOINTMENT OF SENIOR ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified Medical Men for the position of Senior Assistant Medical Officer.

Every applicant must be a registered Medical Practitioner, under 40 years of age, and unmarried.

Applicants must have held Resident Hospital and Sanatorium appointments, and have had practical experience in the diagnosis and modern methods of treatment of tuberculosis; practical experience in radiology is desirable.

Salary £500 per annum, with board, residence, and laundry in addition.

The successful candidate would be required to take up duty on January 1st, 1930.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope, "Medical Officer, Baguley Sanatorium," must be addressed to the undersigned only, and not to members of the Committee or Council, and must reach him not later than Monday, the 28th instant.

The gentleman appointed will be required to pass a medical examination, to devote the whole of his time to the duties of his office, to take charge in the absence of the Medical Superintendent, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order,
F. E. WARBRECK HOWELL,
Town Clerk.

Town Hall, Manchester. October 7th, 1929.

Liverpool County Borough.

LOCAL EDUCATION AUTHORITY.

JUNIOR ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited for a JUNIOR ASSISTANT SCHOOL MEDICAL OFFICER in the Department of the Medical Officer to the Local Education Authority, at a salary of £600 per annum.

Applicants must be registered Medical Practitioners, and shall have had at least three years' experience. It is desirable that they should have had some special experience in School Hygiene and in Diseases of Children.

The officer appointed will be required to devote his whole time to the service of the Education Authority, under the direction of the Medical Officer to the Education Authority. He will not be allowed to undertake private practice, and will be required to contribute to the Liverpool Corporation Superannuation Scheme, as required by the Standing Orders of the City Council.

A form of application may be obtained from the undersigned, and applications, endorsed "Junior Assistant School Medical Officer," must be delivered at the office of the Town Clerk, Municipal Buildings, Liverpool, on or before November 4th.

Canvassing of members of the Committee or the City Council is strictly prohibited, and will be considered a disqualification.

WALTER MOON,
Town Clerk and Clerk to the Local Education Authority.

Municipal Buildings, Liverpool
Oct. 17th, 1929.

City of Manchester.

PUBLIC HEALTH DEPARTMENT.

BAGULEY SANATORIUM. (333 Beds.)

APPOINTMENT OF ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified Medical Men for the position of Assistant Medical Officer.

Every applicant must be a registered Medical Practitioner, under 40 years of age, and unmarried.

Preference will be given to applicants with previous Hospital experience; some experience of bacteriology or radiology is desirable.

Salary £350 per annum, with board, residence, and laundry in addition.

The appointment is made in the first instance for a period of twelve months, renewable at the expiration of that period.

Every application, stating fully the training, qualifications, and experience of the candidate, and his age, with copies of three recent testimonials, and endorsed on the envelope "Medical Officer, Baguley Sanatorium," must be addressed to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester, only, and not to members of the Committee or Council, and must reach him not later than Monday, October 28th.

The gentleman appointed will be required to pass a medical examination, to devote the whole of his time to the duties of the office, to contribute to the Corporation Superannuation Fund, and to execute the Deed of Service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

By Order,
F. E. WARBRECK HOWELL,
Town Clerk.

Town Hall, Manchester. October 7th, 1929.

Monmouthshire County Council.

ASSISTANT MEDICAL OFFICER.

The Council invite applications from duly qualified Medical Practitioners holding a Diploma in Public Health and State Medicine, and not exceeding 35 years of age, for the appointment of Assistant Medical Officer (woman), to undertake mainly the work associated with (1) the Medical Inspection and Treatment of School Children; (2) Maternity and Child Welfare; and (3) the assessment of vision under the Blind Persons Act, 1920.

Special experience in refraction and ophthalmic work is essential.

Salary £500 per annum, rising by annual increments of £25 to £750, with third-class rail fares and reasonable subsistence allowance.

The successful candidate will be required to act under the direction and supervision of the County Medical Officer, to devote whole time to the service of the County Council, and to reside in such place as the Council may determine.

The requisite statutory meeting of the County Council has adopted the Local Government and Other Officers Superannuation Act, 1922, and when confirmed by the Minister of Health the post will be subject, as and from April 1st, 1930, to the provisions of the Act.

A schedule of the duties to be performed, together with conditions of appointment, and form of application, can be obtained from the undersigned, to whom applications, accompanied by copies of not more than three recent testimonials, are to be sent by November 1st.

D. ROCYN JONES,
County Medical Officer.

County Hall, Newport, Mon.
October 7th, 1929.

County Borough of St. Helens.

TUBERCULOSIS OFFICER.

Applications are invited for the above post. Duties will be mainly in connection with the Authority's Tuberculosis Scheme, including those of Resident Medical Officer at the Council's Tuberculosis Sanatorium, but the selected candidate will be required to perform such other duties as the Medical Officer of Health may direct.

Candidates must have had special experience in Tuberculosis (both pulmonary and non-pulmonary) from both clinical and administrative aspects, and the possession of a Diploma in Public Health is desirable.

Salary £600 per annum, with board-residence.

The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and to the successful candidate passing the necessary medical examination.

Forms of application may be obtained from the Medical Officer of Health, Town Hall, St. Helens, and completed applications, accompanied by copies of not more than three recent testimonials, should reach him not later than Saturday, October 26th.

FRANK HAUXWELL,
Medical Officer of Health.

Town Hall, St. Helens.

NOTICE OF ELECTION.

MEDICAL ACT, 1886. (49 and 50 Vict. Ch. 48.)

NOTICE IS HEREBY GIVEN that, pursuant to the Medical Act, 1886, an ELECTION of TWO MEMBERS of the General Council of Medical Education and Registration of the United Kingdom, to represent the registered Medical Practitioners resident in ENGLAND, is about to be held.

Every registered Medical Practitioner is qualified to be nominated as a candidate.

Each candidate must be nominated by a separate nomination paper.

Every registered Medical Practitioner resident in England is entitled to take part in nominating two candidates.

Every nomination paper must state the name, registered address, and registered qualification or qualifications of the candidate nominated; it must be signed by not fewer than twelve registered Medical Practitioners resident in England, as nominating such candidate; and the registered address and registered qualification or qualifications of each one so signing must be appended to his signature.

Every nomination paper, accompanied by a declaration in writing signed by the person nominated, acknowledging that he consents to be nominated, must be delivered, by post or otherwise, on or before the seventh day of November, 1929, addressed to MR. NORMAN C. KING, the Registrar, at the Medical Council Office, 44, Hallam Street, London, W.1, where forms of nomination papers may, on application by post or otherwise, be obtained.

Every nomination paper in respect of which any of these Regulations has not been complied with, or which is not received at 44, Hallam Street, London, W.1, on or before Nov. 7th, 1929, will be invalid.

DONALD MACALISTER,
President of the General Medical Council, Returning Officer.

NOTICE OF ELECTION.

MEDICAL ACT, 1886. (49 and 50 Vict. Ch. 48.)

NOTICE IS HEREBY GIVEN that, pursuant to the Medical Act, 1886, an ELECTION of ONE MEMBER of the General Council of Medical Education and Registration of the United Kingdom, to represent the registered Medical Practitioners resident in SCOTLAND, is about to be held.

Every registered Medical Practitioner is qualified to be nominated as a candidate.

Each candidate must be nominated by a separate nomination paper.

Every registered Medical Practitioner resident in Scotland is entitled to take part in nominating one candidate.

Every nomination paper must state the name, registered address, and registered qualification or qualifications of the candidate nominated; it must be signed by not fewer than twelve registered Medical Practitioners resident in Scotland, as nominating such candidate; and the registered address and registered qualification or qualifications of each one so signing must be appended to his signature.

Every nomination paper, accompanied by a declaration in writing signed by the person nominated, acknowledging that he consents to be nominated, must be delivered, by post or otherwise, on or before the seventh day of November, 1929, addressed to MR. T. H. GRAHAM, the Registrar, at 12, Queen Street, Edinburgh, where forms of nomination papers may, on application by post or otherwise, be obtained.

Every nomination paper in respect of which any of these Regulations has not been complied with, or which is not received at 12, Queen Street, Edinburgh, on or before November 7th, 1929, will be invalid.

DONALD MACALISTER,
President of the General Medical Council, Returning Officer.

NOTICE OF ELECTION.

MEDICAL ACT, 1886. (49 and 50 Vict. Ch. 48.)

NOTICE IS HEREBY GIVEN that, pursuant to the Medical Act, 1886, an ELECTION of ONE MEMBER of the General Council of Medical Education and Registration of the United Kingdom, to represent the registered Medical Practitioners resident in IRELAND, is about to be held.

Every registered Medical Practitioner is qualified to be nominated as a candidate.

Each candidate must be nominated by a separate nomination paper.

Every registered Medical Practitioner resident in Ireland is entitled to take part in nominating one candidate.

Every nomination paper must state the name, registered address, and registered qualification or qualifications of the candidate nominated; it must be signed by not fewer than twelve registered Medical Practitioners resident in Ireland, as nominating such candidate; and the registered address and registered qualification or qualifications of each one so signing must be appended to his signature.

Every nomination paper, accompanied by a declaration in writing signed by the person nominated, acknowledging that he consents to be nominated, must be delivered, by post or otherwise, on or before the seventh day of November, 1929, addressed to MR. RICHARD J. E. ROE, the Registrar, at 35, Dawson Street, Dublin, where forms of nomination papers may, on application by post or otherwise, be obtained.

Every nomination paper in respect of which any of these Regulations has not been complied with, or which is not received at 35, Dawson Street, Dublin, on or before November 7th, 1929, will be invalid.

DONALD MACALISTER,
President of the General Medical Council, Returning Officer.

Hackney Hospital.

The Guardians of the Hackney Union invite applications from duly qualified gentlemen for the position of JUNIOR ASSISTANT MEDICAL OFFICER (Physician).

Candidates must be single, and must have held previous resident Hospital appointment.

The Hospital, which is situate at High Street, Homerton, E.9, contains 800 beds, and is equipped with modern requirements.

Besides the Medical Superintendent, there are six Resident Medical Officers and a Clinical Pathologist.

The remuneration is at the rate of £350 per annum, rising by £25 annually to a maximum of £375 per annum, together with allowances, washing, furnished apartments, and attendance.

The duties of the officer appointed will be mainly on the medical side of the Hospital, but he will also be required to render assistance at the other establishments and departments of the Union, to assist in the training and instruction of nurses, and to devote the whole of his time to the service of the Guardians.

The appointment will be subject to the provisions of the Poor Law Officers Superannuation Act, 1896.

Further particulars as to the duties may be obtained from the Medical Superintendent.

Canvassing the Guardians, directly or indirectly, will disqualify candidates.

Applications must be made upon forms which are obtainable from the undersigned.

The forms must be completed and returned, with copies of not more than three recent testimonials, by Monday, November 4th, 1929.

By Order,
E. W. HARBOUR,
Clerk to the Guardians.

Clerk's Office,
Hackney Union,
Homerton, E.9.

St. Mary's Hospital, W.2.

The Board of Management are prepared to receive applications for the post of ASSISTANT SURGEON for Diseases of the Ear, Nose, and Throat.

Applicants for the appointment are requested to forward their applications, addressed to the Secretary at the Hospital, so that they shall reach him on or before October 31st.

Candidates must be Fellows of the Royal College of Surgeons of England, or must undertake to become so within six months.

The Supernumerary Assistant Surgeon for Diseases of the Ear, Nose, and Throat is a candidate for the post.

By Order,
W. PARKES,
Secretary.

October 14th, 1929.

St. Mary's Hospital, W.2.

The Board of Management are prepared to receive applications for the post of ASSISTANT OPHTHALMIC SURGEON.

Applicants for the appointment are requested to forward their applications, addressed to the Secretary, at the Hospital, so that they shall reach him on or before October 31st.

Candidates must be Fellows of the Royal College of Surgeons of England, or must undertake to become so within six months.

The Supernumerary Assistant Ophthalmic Surgeon to the Hospital is a candidate for the post.

By Order,
W. PARKES,
Secretary.

October 14th, 1929.

South Yorkshire Mental Hospital,

SHEFFIELD.

Wanted, MEDICAL OFFICER (male) not over 35, unmarried. Salary £400, rising £25 a year to £500, with board, etc. The appointment is made subject to the provisions of the Asylums Officers' Superannuation Act, 1909. Applications, with three testimonials (copies only), to be sent to the Medical Superintendent on or before November 1st.

St. John's Hospital,

Lewisham, S.E.13.

A vacancy has been declared in the office of RADIOLOGIST to the Hospital, to fill which applications are invited. The successful applicant must be prepared to commence duties at the beginning of November. The conditions of appointment and further information may be obtained from the Secretary at the Hospital, and applications must be received by Oct. 21st.

St. John's Hospital,

Lewisham, S.E.13.

Applications are invited for the office of RESIDENT MEDICAL HOUSE SURGEON for three or six months from November 1st, at a salary of £100 per annum. Applications, with copies of testimonials, should reach the Secretary at the Hospital not later than October 21st. The Selection Committee will sit on October 22nd at 4.30 p.m.

The Hospital for Sick Children,

Great Ormond Street, London, W.C.1.

A RESIDENT MEDICAL OFFICER is required at the COUNTRY BRANCH HOSPITAL, TADWORTH COURT, TADWORTH, SURREY, on November 7th.

Candidates are invited to send in their applications to the Secretary before 12 o'clock on Monday, November 4th, accompanied by copies of not more than three testimonials given specially for the purpose.

The appointment is made for six months, but the successful candidate will be eligible for re-appointment.

Salary at the rate of £250 per annum, with board, residence in the Hospital, laundry allowance at the rate of £10 per annum, and, on re-election for a further period of six months, £18 18s. for the purpose of providing a substitute during annual leave of a maximum of four weeks.

Candidates must be unmarried and possess a legal qualification to practise, and must have held a responsible resident appointment at a General Hospital.

All candidates must be in attendance on Wednesday, November 6th, at 4.45 p.m., precisely, to appear before the Joint Committee, if required.

Forms of application and copies of the Rules may be obtained from the Secretary, at the Hospital.

By order of the Board of Management,
JAMES McKAY, Secretary.

October, 1929.

(121 Beds.)

THIRD HOUSE SURGEON (male) required immediately. Duties include Ophthalmic, Medical, and Casualty work. Opportunity for gaining excellent experience. Appointment is for six months, and successful candidate is eligible for re-appointment and probable promotion.

Salary £150 per annum, with board, residence, and laundry. Applications, with full particulars, should be addressed to the undersigned by Wednesday, October 23rd.

J. LAWRENCE MEARS,
October 16th, 1929. Secretary-Supt.

Parish of Stepney.

RESIDENT ASSISTANT MEDICAL OFFICER.

The Guardians invite applications from duly qualified registered Medical Practitioners for the vacant post of Resident Assistant Medical Officer at their ST. PETER'S (WHITECHAPEL) HOSPITAL, Vallance Road, London, E.1. Salary £450 per annum, together with full residential emoluments valued at £120 per annum for the purposes of superannuation.

Candidates must have previously held a resident House appointment at a Hospital, and the person appointed will be required to work generally under the direction of the Medical Superintendent. Preference will be given to candidates who possess some experience in the treatment of Nervous and Early Mental Disorder.

The appointment is for a probationary period of six months in the first instance; is subject to a medical examination as to physical fitness before commencing duties, and also to any provisions affecting officers in the Local Government Act, 1929.

Forms of application may be obtained from the undermentioned address upon receipt of a stamped addressed foolscap envelope, or by personal application to the Medical Superintendent at the Hospital, and must be returned to this office by not later than Monday, October 28th.

By Order,
S. McCLELLAND,
Clerk to the Guardians.

Administrative Offices,
Bancroft Road,
Mile End, E.1.
October 9th, 1929.

Leicestershire County Council.

ASSISTANT COUNTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified Medical Practitioners (male) under 40 years of age, for the appointment of Assistant County Medical Officer.

Candidates must possess a Diploma in Public Health; experience in School Medical Inspection and Public Health administration will be deemed additional qualifications.

The person appointed must devote the whole of his time to the duties of the office, and will carry out such other duties as the County Medical Officer may assign to him.

The salary will be at the rate of £650 per annum, rising, subject to satisfactory service, by annual increments of £25 to £700, per annum, with travelling expenses according to the County Council scale.

The appointment is subject to the Local Government and Other Officers Superannuation Act, 1922.

The appointment will be terminable by three months' notice on either side.

Forms of application may be obtained from the undersigned, and should be returned, accompanied by copies of not more than three recent testimonials, by Friday, November 1st.

W. J. FREER,
Clerk to the Council.

10, New Street,
Leicester.
October 14th, 1929.

Prison Medical Service.

Applications are invited for the post of MEDICAL OFFICER, CLASS II, in the above service. Salary £350, rising by £20 per annum to £600, with quarters, or an allowance in lieu. The pay is subject to a bonus, which at present on a salary of £350 is £135 8s. These posts are pensionable, and there are prospects of promotion to higher rank.

Candidates must be fully qualified and registered. Preference will be given to those who have held House appointments, have had experience in Lunacy and Psychological methods, and are under the age of 30. Forms of application can be obtained from the Secretary, Staff Branch, Prison Commission, Home Office, London, S.W.1.

City of Birmingham.

MEDICAL OFFICER FOR MATERNITY AND CHILD WELFARE.

The Public Health Committee invite applications from Medical Women for the post of Medical Officer for Maternity and Child Welfare. Applicants must have had Children's Hospital and Maternity Hospital experience. The Diploma of Public Health is desirable. Salary £600 per annum. The appointment will be terminable by one month's notice on either side. Applications endorsed "Medical Officer for Maternity and Child Welfare," and accompanied by copies of three recent testimonials, to be made on a form to be obtained from the Medical Officer of Health, Council House, Birmingham, and returned to him on or before November 2nd. Canvassing will disqualify.

Devon County Council.

APPOINTMENT OF TUBERCULOSIS OFFICER FOR NORTH DEVON.

Applications are invited for the appointment of Tuberculosis Officer (Clinical) for the Barnstaple Dispensary Area of the County of Devon.

The salary will commence at £750 per annum, and travelling expenses will be allowed in accordance with Grade A of the Council's Scale, the officer to provide his own motor car, also to contribute to the Council's Superannuation Scheme.

The officer appointed will be required to devote the whole of his time to his official duties and will not be permitted to accept any fee or present of any description.

Forms of application and further particulars can be obtained from the undersigned, and must be returned endorsed "Tuberculosis Officer," and accompanied by not more than three recent testimonials, not later than the first post on October 26th.

The Castle,
Exeter.
October 4th, 1929.

BRIAN S. MILLER,
Clerk of the County Council.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(Founded 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele Address: Triform, Wesdo—London. Telephone: Mayfair { 1782 / 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Full Schedule of Terms and Conditions will be forwarded on application.

$C_8 H_{10} N_4 O_2 + H_2 O$

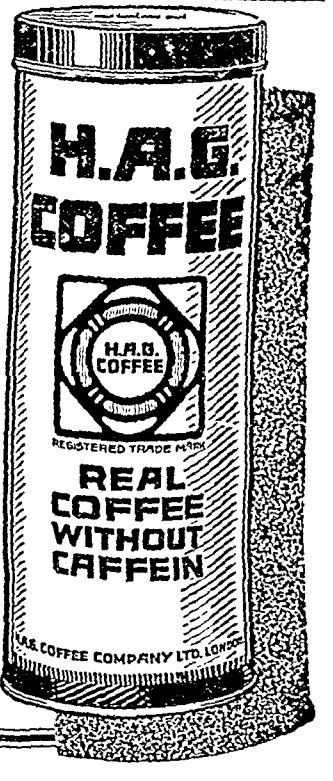
THE injurious action of caffein, to which the ailing, reconvalescents and those in good health become liable by the habitual or excessive consumption of coffee and tea, is causing an increased interest in the medical world. There is already a comprehensive literature dealing with this subject; in many cases it absolutely bans the consumption of beverages containing caffein.

THE physician who is solicitous with regard to the welfare and ailments of his patients will specially value the knowledge that **H.A.G. COFFEE**—a caffein-free berry coffee—is obtainable, which in respect to aroma and palatableness, affords the same sense of enjoyment as ordinary coffee containing caffein, but without its harmful action on the cardiac, the nervous, and the vascular system.

WITH **H.A.G. COFFEE** the caffein is extracted from the unroasted coffee bean by a patented process, until only a slight, non-effective trace remains. Previous to this treatment, the coffee beans undergo a most thorough cleansing.

CAFFEIN-free **H. A. G. COFFEE** can confidently be recommended as the best and most valuable health coffee, and, in order to give members of the Medical Profession an opportunity of personally appreciating the hygienic characteristics of **H.A.G. COFFEE**, we shall be pleased to send a sample and literature free on request.

H.A.G. Coffee can be obtained in 2 sizes, price 3/2 and 1/8, either ground or in the bean. If your grocer has no stock we will supply post free upon receipt of your remittance



H.A.G. COFFEE CO. LTD.
40 Theobald's Road, London, W.C.1

Valentine's Meat-Juice

In the **Gastric Form of Influenza** and its **Debility**, in **Typhoid** and **Acute Pneumonia**, in the **Exhaustion** of **Phthisis** and **Pulmonary Diseases**, **Valentine's Meat-Juice Sustains** and **Strengthens**

When Other Food Fails

THE quickness and power with which VALENTINE'S MEAT-JUICE acts, the manner in which it adapts itself to and quiets the irritable stomach, its agreeable taste, ease of administration and entire assimilation recommend it to physician and patient.

Physicians are invited to send for brochures containing clinical reports.

For sale by European and American Chemists and Druggists.

"IMPROVEMENT IN HEALTH IN A FEW DAYS."

(3D) "I take Bemax myself and have continued to take it as I find it so beneficial. I take it with porridge and milk. When I began taking Bemax the effect was noted in a few days. I felt better and stronger, and better able to bear fatigue. I have much pleasure in recommending it to my patients and I have had pleasing results." M.D., D.P.H.

(4D) "I have prescribed Bemax for patients suffering with debility after influenza. There was general improvement in health in a few days." M.B., B.S.

Bemax is now established as the B vitamin food. Over 34,000 members of the medical profession in Great Britain have applied for Bemax for personal trial. The diseases for which medical men are prescribing Bemax are Constipation, Intestinal Toxæmia, Debility, Neurasthenia, Rheumatism, Gastric disturbances, and all forms of skin disease. In fact, any ailment due to B-vitamin deficiency. If you have not tried Bemax, a free full-size tin will be sent you on receipt of your professional card.

J. & A. CHURCHILL

THREE NEW EDITIONS

SECOND EDITION. 271 Illustrations, 4 Coloured Plates. 18s., postage 9d.

THE QUEEN CHARLOTTE'S PRACTICE OF OBSTETRICS

By J. B. BANISTER, M.D., C. S. LANE-ROBERTS, M.S., A. W. BOURNE, M.B., L. G. PHILLIPS, M.S., T. B. DAVIES, M.D., L. C. RIVETT, M.C., F.R.C.S.
(Members of the Staff of the Hospital).

FIFTH EDITION. 1,051 pages. ONE GUINEA. Postage 1s.

STARLING'S PHYSIOLOGY

Edited and Revised by C. LOVATT EVANS, D.Sc., F.R.C.P., F.R.S., Jodrell Professor of Physiology in University College, London. With chapters on the Central Nervous System and Sense Organs revised by H. HARTRIDGE, M.A., M.D., Sc.D., F.R.S., Professor of Physiology, St. Bartholomew's Medical College.

FIFTH EDITION, 48 Illustrations. 12s. 6d., postage 6d.

RECENT ADVANCES IN MEDICINE

B. G. E. BEAUMONT, D.M., F.R.C.P., Physician, Middlesex Hospital; and E. C. DODDS, M.D., M.R.C.P., Professor of Biochemistry in the University of London.

175 Illustrations. 16s., postage 9d.

PRACTICAL MIDWIFERY

By GIBBON FITZGIBBON, M.D., Late Master, Rotunda Hospital, Dublin.

"A book from the Master of the Rotunda Hospital, Dublin, can never be neglected, and a book on practical midwifery is likely to be particularly informing. An instructive book. . . . Stimulating and useful."—ST. BART.'S HOSP. JOUR.

NINTH EDITION. 73 Illustrations. 24s., postage 9d.

CUSHNY'S PHARMACOLOGY AND THERAPEUTICS, OR THE ACTION OF DRUGS IN HEALTH AND DISEASE

Thoroughly revised by C. W. EDMUNDS, A.B., M.D., Professor of Materia Medica, University of Michigan; and J. A. GUNN, M.D., D.Sc., Professor of Pharmacology, University of Oxford.

THIRTEENTH EDITION. 1,063 pages. 48 Plates (8 coloured). 92 Text-figures 28s., postage 1s.

TAYLOR & POULTON'S MEDICINE

Sections on Neurology by C. P. SYMONDS, M.D., and on Skin by H. W. BARBER, M.B., F.R.C.P.

"No text-book of medicine is quite so comprehensive as 'Taylor's,' and none deserves a greater popularity."—BIRM. MED. REVIEW.

TWELFTH EDITION. 68 Illustrations. 28s., postage 9d.

GOODHART & STILL'S DISEASES OF CHILDREN

"The present edition will carry on for a further period the life and service of a British medical classic."—BRITISH MEDICAL JOURNAL.

SECOND EDITION. 5s.; postage 3d.

FAVOURITE PRESCRIPTIONS

Including Dosage Tables and Hints for Treatment of Poisoning.

By ESPINE WARD, M.D., Fellow Royal Society of Tropical Medicine and Hygiene.

307 Illustrations. 36s. net, postage 9d.

THE NEMATODE PARASITES OF VERTEBRATES

By WARRINGTON YORKE, M.D., and P. A. MAPLESTONE, M.D., D.S.O.
Foreword by C. W. STILES, Professor of Zoology, U.S. Public Health Service.

126 Illustrations. 30s., postage 9d.

THE MODERN PRACTICE OF PEDIATRICS

By W. PALMER LUCAS, M.D., LL.D., Prof. of Pediatrics, University of California.

SECOND EDITION. 8 Coloured Plates. 92 Illustrations. 18s., postage 9d.

MOORE'S MEDICAL OPHTHALMOLOGY

"As a connecting link between the specialized science of ophthalmology and the wider scope of general medicine, it is unsurpassed in our literature for its conciseness and clarity and its wealth of detail."—BRITISH MEDICAL JOURNAL.

2 Plates and 123 Text-figures. 15s., postage 7d.

WOOD JONES' PRINCIPLES OF ANATOMY AS SEEN IN THE HAND

"One of the most notable contributions ever made to the literature of British anatomy . . . places the author in the first rank of British anatomists."—BRITISH MEDICAL JOURNAL.

117 Illustrations. 30s., postage 9d.

JACKSON'S EFFECTS OF INANITION AND MALNUTRITION UPON GROWTH AND STRUCTURE

By C. M. JACKSON, M.S., M.D., LL.D., Professor of Anatomy, University of Minnesota.

THIRD EDITION. 59 Illustrations. 25s., postage 9d.

EXAMINATION OF WATERS AND WATER SUPPLIES

By J. C. THRESH, M.D., and J. F. BEALE, M.R.C.S., L.R.C.P., D.P.H.

"The book is a work of sheer merit. The more it is consulted the greater is the appreciation of the whole-hearted work the authors have done."—THE ANALYST.

Re VOL. II.

JUST PUBLISHED.

EXTRA PHARMACOPŒIA

By

W. HARRISON MARTINDALE, Ph.D.

759 + xxxviii pp. *22/6 net; post free, 23/-.*

Medical Men who possess Vol. I., issued last July, will find the additional Volume of greatest utility.

IT COMPLETES THE SET.

Volume II. is concerned with **EXPERIMENTAL RESEARCH** and **DIAGNOSIS** of most divers types.

The **FIRST 170 PAGES** (approx.) are concerned with important investigations of drugs and chemicals—e.g., **Arsenicals, Digitalis, Indigo-Carmine, Mercurochrome, Dye Elimination Tests for Liver and Kidney, Quinine, Ephedrine, New Pituitary Research,** etc., with which the up-to-date medical man must keep *au fait.*

The Chapter on **RADIUM** (30 pages) deals with the 'Commerce' of the Element to-day, Properties, Theory of Radio-Activity, Therapy of the Element and of **Radon,** and Containers for their employment.

The Section on **RADIOLOGY** (30 pages) embodies latest directions on 'Meals,' Diagnosis, Reviews of Treatment in alphabetical order, **Ultra-Violet Rays** and their uses and limitations..

The **CLINICAL ANALYSIS** Section (60 pages) is remodelled and contains reliable tests for detection of pathological constituents of the Urine, Fæces, etc., and methods of evaluating Renal Function and Blood Sugar.

The **WATER EXAMINATION** Section occupies 40 pages and embodies an important and interesting discussion on Iodine in relation to Goitre throughout the world.

MILK EXAMINATION and the entire subject of Milk Supply is thoroughly considered from various aspects in 30 pages.

FOOD PRESERVATIVES bring out an interesting examination regarding **MOULD INHIBITION.**

BACTERIOLOGICAL and **CLINICAL NOTES** on Special Diseases from Acne to Yellow Fever occupy 112 pages and contain many recent references.

Other matters dealt with are **Vitamins, Synthetic Chemicals** and their Physiological Effects, **Sophistication of Foods.**

From the **Legal Aspect** the work is useful; many recent enactments are given in brief.

The Work in its 2 Vols. is recognised to be of unique value as an up-to-date Reference Book in everything appertaining to the Therapeutic Use of Drugs. It embodies the Latest and Most Varied Information on Chemistry, Pharmacy, Therapy, and Allied Sciences.

Both Vols. can be forwarded together to any part of the world, price **50/- net, post free. Volume I, 27/6 net. Volume II, 22/6 net. Postage 6d. each.**

London: H. K. Lewis & Co. Ltd., 136, Gower Street, W.C.1.

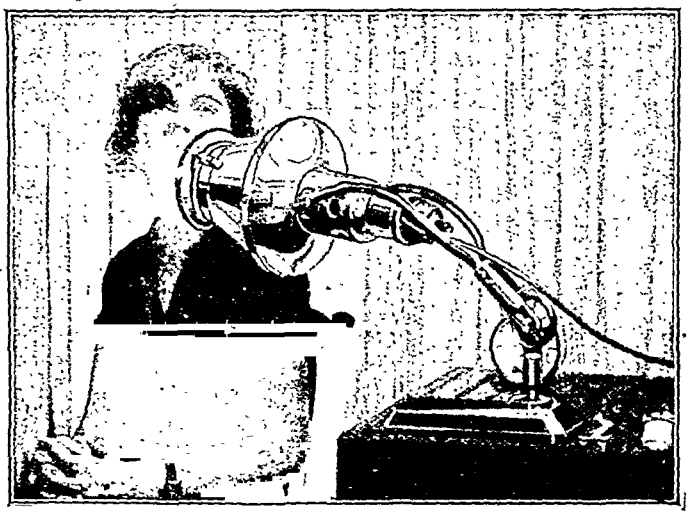
Practitioners' Problems



THE HANOVIA SOLLUX LAMPS
are ideal equipment for the therapeutic application of luminous heat rays.

Number 9

Acute Catarrhal Conditions

"Light therapy soothes the part, relieves spasm and pain, and have proved clinically to be far more beneficial than the application of heat from without by such local applications as poultices, counter-irritants, hot compresses, and hot water bottles, etc. Clinical experience shows that the application of radiant light and heat energy produces an active hyperaemia, relieves the sense of fullness and congestion, enhances local nutrition, soothes the pain, and promotes comfort when applied to the facial regions for relief of coryza, rhinitis, acute and sub-acute sinusitis, catarrhal deafness, and otitis media."
(Dr. C. R. Brooke, M.D., Physical Therapeutics, June, 1929.)

SURGICAL SERVICE
SALTAIR

SALTAIR SURGICAL SERVICE

Guarantee

"We guarantee to alter, exchange, or accept the return of any appliance without cost, ordered by the Medical Profession, if not found suitable within fourteen days from date of supply."

Salt and Son Ltd.

PIONEERS

MEDICAL opinion of to-day pays great tribute to the Pioneers of Surgery who—with crude appliances and knowledge—blazed the trail upon which Modern Surgical Science is firmly established.

136 years ago the HOUSE of SALT recognised the fact that "Rule of Thumb" methods could never meet specialised surgical requirements.

From this Standard SALTS have never departed. To-day—as in the Past—

SALTAIR SURGICAL SERVICE

acts in co-operation with the Medical Profession —making each appliance specially to individual requirements as specified by the Medical Man.

SALT AND SON LTD.
7, CHERRY ST., BIRMINGHAM.

COPYRIGHT

ESTABLISHED 1793.

INFLUENZAL "COLDS"

Alkaline therapy in some form has given the best results in all the recent epidemics of influenza and colds. The particular form of alkaline therapy represented by the administration of SALVITAE has always, when given a fair trial, proved to be the most dependable resource of all.

Samples and Literature on request to Sole Agents: COATES & COOPER, 41, Great Tower Street, London, E.C.3.

A formula that demonstrates its scientific value.

Salvitae

Two sizes, 4/- and 7/6.

Manufactured by American Apothecaries Co., New York.

FOR INTERNAL TREATMENT OF GONORRHŒA, URETHRITIS, AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT.

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal Wood, the oil is bland and remarkably

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS

which are provoked by many preparations.

There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract.

The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Générale, 8, Rue Vivienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World.

U.K. Agents: WILCOX, JOZEAU & Co., 15, Gt. St. Andrew St., W.C.2

EATAN

Pronounced E-TAN

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non-irritant. Dr. Haff, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the body tissues, when the natural processes of metabolism fail to function normally.

A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for invalids.

Issued in 2/6, 4/-, and 10/8 bottles.

Test sample & Literature sent free on application to

A. DEBUZ, St. BRELADE, JERSEY.

COLONIC LAVAGE

A SUGGESTED IMPROVEMENT IN THE PLOMBIÈRES TREATMENT

By

Capt. J. T. AINSLIE-WALKER,

R.A.M.C. (T.F.), F.I.C., F.C.S.

Extract from "The Medical Press," November 7th, 1923:

"As is generally known, the Plombières treatment in cases of colitis and other forms of intestinal disorders is now largely resorted to. Its increasing vogue has been chiefly due to its results, favourable up to a certain point, but incomplete in a particular detail, which militates against a curative effect. The principle upon which the lavage method rests is to remove the bowel contents by means of irrigation at regular intervals. Thus the whole process is a mechanical one, and it leaves out of account the toxin-producing bacteria of the intestines, which still remain after the irrigation. Captain Ainslie-Walker makes a valuable suggestion in his brochure by which this difficulty can readily be overcome. In the course of his researches the fact has been established that an ordinary Plombières solution, after expulsion from the bowel, shows confluent growth, but under the same circumstances a Plombières solution in which Dimol powder has been previously dissolved *shows no growth.* The experiments are described by which these results were obtained. By the simple method, therefore, of adding this intestinal bactericide—Dimol—to the Plombières solutions the circle of effective treatment is made complete."

Copies of this brochure will be sent, free of charge, on application to the

Dimol Laboratories, 40, Ludgate Hill, London, E.C.4.

ASSISTANCE FOR THOSE TREATING SKIN COMPLAINTS

The lessons of the great war added nothing more clearly to the knowledge of the treatment of skin troubles than a realisation of the healing virtues of peat. Used for wounds and for skin diseases, this natural remedy met with the most gratifying success. You can use it conveniently and cheaply if you select from the list of Sphagnol preparations whichever is most suitable for your purpose. There is an ointment, soaps (medical, toilet, and shaving), suppositories, and a lotion. All contain 5, 10, or 15 per cent. of the principle in a medium of the highest quality. All are obtainable from your own chemist.

In order that you can test their efficacy the makers are always glad to send free samples to medical practitioners who write to Peat Products (Sphagnol) Ltd. (Dept. B17), 21, Bush Lane, London, E.C. 4.

A special food for changing the intestinal flora

Lactose and Dextrin owe their value in changing the intestinal flora to the fact that they are more slowly absorbed than other carbohydrates. Because of this slow absorption they are able to reach the colon in sufficient quantity to cause a luxuriant growth of productive flora, thus keeping down putrefactive and poison-forming germs.

Lacto-Dextrin effectively disposes of the disadvantages of both Lactose and Dextrin in their crude form. It is a palatable and agreeable combination of the two, and is highly efficient in producing the growth and development of both B. acidophilus and B. bifidus in the colon.

Samples and literature will be sent on request to the Medical Profession on application to Sole Distributing Agents for U.K. and Irish Free State, COATES & COOPER, 41, Great Tower Street, London, E.C.3.

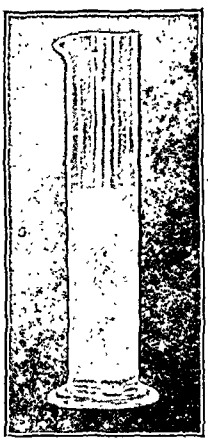
The 'Allenburys' DIET

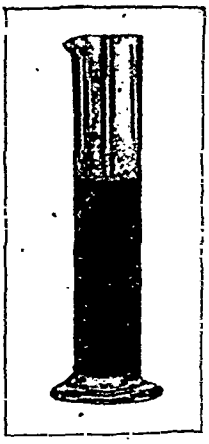
A Stimulating and Sustaining Food Beverage



A Showing the heavy curd formed by the action of gastric juice on ordinary cow's milk.

A solution to the problem of feeding in many acute and chronic affections is found in the use of the 'Allenburys' Diet, which presents distinct advantages over cow's milk both with regard to food value and digestibility. The 'Allenburys' Diet is a palatable and highly nutritive food beverage prepared from pure fresh full-cream milk and whole wheat, and is particularly easy of assimilation. It replaces with advantage milk and the milk dishes commonly employed in sickness and convalescence and can often be taken and retained where other foods are rejected. As a stimulating and sustaining beverage for people of all ages, it is infinitely superior to tea, coffee, etc. It can be made in a minute simply by adding either boiling water or milk.

In tins at 2/1, 4/- and 7/6.



B Showing the finely flocculent curd formed by the action of gastric juice on the 'Allenburys' Diet.

Descriptive Literature and free clinical sample will be gladly sent on request.

Calcium Deficiency in Expectant & Nursing Mothers

Pregnancy and lactation often produce manifestations of calcium deficiency because the calcium reserve cannot meet the demands made upon it. The systematic use of Kalzana in these cases stays the destructive processes in the teeth and bones of the mother, and ensures normal development of the skeletal structure of the infant. The special feature of Kalzana is that it combines calcium lactate and sodium lactate in the form of a double salt, with the result that the sodium element improves the blood alkalinity to the extent necessary to ensure adequate calcium retention.

"The Practitioner" says:

"Kalzana acts efficiently in promoting the growth of strong bones and healthy teeth, in protecting the expectant and nursing mother against a dangerous loss of calcium . . . . particularly because Kalzana promotes calcium retention."

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

calcium-sodium-lactate

Also supplied *direct* for Doctor's own dispensing at 15/- per 1000 plain tablets.

FOOD POISONING—
THE KAYLENE TREATMENT

The following letter has been received recently.

Messrs. Kaylene, Ltd. April 17th, 1929.

Dear Sirs,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him only Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Physician to ———. Yours faithfully, ———, M.B.

RADIOSTOLEUM

The Anti-infective Agent

Issued as a liquid and in capsules

Results of recent investigations have demonstrated the value of Radiostoleum as an anti-infective agent—quite apart from its action in the prevention and cure of rickets and in the promotion of healthy growth.

Whilst these investigations were confined to specific cases of puerperal septicæmia, the use of Radiostoleum in practice is being extended to a wider field, particularly in the prophylaxis of acute infections of the lungs, such as pneumonia.

Precise activity, unvarying in effect, is an essential factor in the success achieved by this new therapy. Radiostoleum is scientifically-standardised in regard to Vitamins A and D; it can be administered with the full assurance that not only will it produce uniformly beneficial results, but that possibilities of deleterious effects such as hypercalcæmia and hyperphosphatæmia will be precluded entirely.

Successful Treatment of Hyperchlorhydria and Associated Conditions

"Alocol" (Colloidal Hydroxide of Aluminium) has proved remarkably successful in the treatment of hyperchlorhydria, gastric ulcer, fermentative dyspepsias with gastro-intestinal flatulence, acid eructation and other symptoms common to gastric disease.

The advantages of "Alocol" are that it actually removes from the system the causative acid radicle (Cl) instead of merely neutralising it, and so permitting reabsorption, accumulation and consequent recurrence of the symptoms of the disease.

Furthermore, "Alocol" neither hinders proteolysis nor causes destruction of any food element or factor. "Alocol" has a distinct healing and sedative effect; it promptly allays irritation by absorbing acid and other irritants.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

A valuable asset in Treating Nervous Ailments

Every Doctor knows the value of specific treatment in illness, and one of the greatest difficulties in treating nervous troubles hitherto has been the absence of a specific remedy for debilitated nerve cells and tissues.

"NEW-PROMONTA" is not only a specific remedy, but also a very speedy and reliable one, as has been proved by exhaustive tests in many hospitals and clinics and in private practice.

The active agents in "NEW-PROMONTA" are the Lipoids, Phosphatides, and Cholesterols, which by a special process of preparation are preserved intact and in the same quantity as they are found in the living cells of nerves and brain.

"NEW-PROMONTA", is valuable in other directions. It contains a high proportion of concentrated nutritives, including Lime, Iron, Hæmoglobin, and the Vitamins A, B, D, and E. It is therefore a powerful factor in promoting general robustness, in counteracting the after-effects of illness, and during convalescence.

TO TEST "NEW-PROMONTA."

A trial supply of "NEW-PROMONTA," together with a collection of authoritative data on its composition and the tests to which it has already been subjected, will be sent post free to any Doctor, Clinic, or Hospital on application.

"NEW-PROMONTA" in Tablet form is supplied in handy boxes containing 54 tablets at 3/6. Each box includes a metal container for the pocket, which holds a day's supply.

"NEW-PROMONTA" in Powder form is supplied in sealed air-tight boxes of ½-lb. at 3/- and ¼-lb. at 5/6.

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Science once more endorses HOVIS

IRREFUTABLE EVIDENCE

Scientific Research into the essential factors underlying the bread question has brought to light certain facts of the highest practical value to medical men as well as to the general public.

HOVIS is shown, from an analysis of many experiments, not only to possess a larger content of the vital element Vitamin B than other breads, but provides more positive nourishment for the quantity consumed.

One slice of HOVIS weighing 1 oz. contains as much Vitamin as 2 oz. of wholemeal, or 5 to 6 g. of fresh yeast; white bread contains only about 2 per cent. of yeast.

It is also found that "brownness" of bread is no measure of the Vitamin content.

The Wheat Germ the secret of Hovis Nutrition

By blending the finest white flour with 25 per cent. wheat germ, HOVIS combines the goodness of the one with the rich Vitamin B qualities of the other. Further, containing no bran, it is very easily digested.

These facts all point to one conclusion: that in dietetic value HOVIS holds the first place for promoting health.

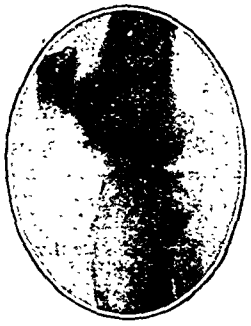
A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies



Radiograph of Knee-joint in Rheumatoid Arthritis

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

"Iodolysin" is a chemical combination of Iodine and Thiosinamin with these special advantages:

Ready Solubility in water. Well tolerated. Absence of local reaction on injection

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.

Intestinal Disinfection

ALIMENTARY TOXÆMIAS

IN our last advertisement, the subject of Alimentary Toxæmia was briefly discussed, and intestinal disinfection by means of Kerol Capsules was held to be the first line of treatment.

The reason for this may be stated as follows:—None of the ordinary so-called intestinal antiseptics, such as Salol and Beta Naphthol, are found experimentally to exert any disinfection of the contents of the bowel.

On the other hand, the high boiling hydroxyl compounds of the coal tar series are potent germicides, and, being unabsorbed, are non-toxic. They can therefore be administered freely without harm, and are found to prevent the multiplication of the toxæmic intestinal bacteria and to reduce them considerably.

The active principle of Kerol is a complex mixture of these compounds. The administration of two 3-minim capsules thrice daily after meals has been repeatedly shown to reduce the coli content of the stools of individuals taking them by 99 per cent.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

The Standard of Purity of

INSULIN "A.B."

TRADE A B MARK Brand

The ideal Insulin should be so pure that its use is entirely free from any untoward effect. This is the aim of the makers of Insulin "A.B.", who have adopted their own stringently high standard of purity and have always maintained it. Reductions in their prices have never involved the slightest sacrifice of quality.

Insulin "A.B." is so pure—and therefore so free from reaction-producing proteins—that the number of clinical units per milligram of substance approaches the maximum possible, i.e., the equivalent of crystalline Insulin.

The world-wide supremacy of Insulin "A.B." is due to this unequivocal purity no less than to its well-known potency and stability under all conditions.

"SMILER"

Vitamins

AND DRIED MILK

THE vital importance of an adequate supply of vitamins in the feeding of infants is now well recognised, not only in the prevention of obvious deficiency diseases such as rickets and scurvy, but also in the maintenance of the general resistance against the common infections of the respiratory, alimentary, and urinary tracts, and the determination of a normal equilibrium between the various endocrine secretions.

Cow & Gate Milk Food

Cow's Milk made safe and suitable for Baby.

The vitamin content of milk depends, in the first instance, on the character of the diet supplied to the cows. English pasture-fed herds furnish a milk superior in its vitamin content to that of stall-fed animals, or those fed on inferior pastures of dry and tropical climes. The Cow & Gate dairy farms and laboratories are situated in the rich pastures of Somerset and Dorset, and thus a high vitamin content of their milk is assured, obviating the necessity for the addition of synthetic vitamin concentrates, which are very doubtful in their action.

The survival of the vitamins in the dried product depends on the process employed. The Cow & Gate Roller process of drying milk involves exposure to heat for a matter of seconds only, with the result that the vitamins are for all practical purposes intact.

There have been no proved cases of rickets where Cow & Gate Milk Food has been used. Many feeding experiments in the hands of well-known investigators have demonstrated that adequate nutrition and growth are assured on a diet of this food, which has now been widely recommended by the Medical Profession for over a quarter of a century.

The makers will gladly supply samples for Clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

COW & GATE Ltd.,

GUILDFORD.

THE ENTIRE GROUP OF NITROGENOUS SUBSTANCES OF LEAN BEEF AND ENTIRE WHEAT GRAIN,

THOSE NATIVELY SOLUBLE AND THOSE RENDERED SOLUBLE BY PHYSIOLOGICAL HYDROLYSIS, AMINO-ACIDS AND POLYPEPTIDS WITH THE NATURAL SAVORY EXTRACTIVES AND MINERALS. THE WHEAT CARBOHYDRATES PHYSIOLOGICALLY CONVERTED TO DEXTRIN AND MALTOSE.

All this Blended in a Calculated Ratio, One of Nitrogenous to Two and One-Half of Carbohydrate, in a Highly Agreeable Fluid.

THIS IS 'PANOPEPTON'—A DYNAMIC FOOD

In the preparation of Panopepton the beef is submitted to the action of gastric juice extract at normal temperature and acidity to a complete conversion of the proteins; the clarified solution concentrated in vacuo.

The hard wheat grain, well cooked like a cereal, is subjected to both proteolytic and amylolytic digestion by a freshly prepared pancreas gland extract at normal media and temperature, until free from coagulable protein and free from starch, the clarified solution concentrated in vacuo. The soluble concentrates of the beef and wheat are combined on the basis of assay.

Thus in Panopepton is assembled this designed comprehensive variety of protein derivatives, highly diffusible, physiologically complementary, mutually helpful in nutrition; of the native wheat-berry—albumen (vegetable), glutin-casein, glutin-fibrin, gliadin, mucedin; of beef—albumen, myosin, connective tissue-protein (source of gelatin), beef extractives, creatin, creatinin, sarcin, xanthin, and inosin. With the natively soluble associated principles, mineral, etc., as well as these principles of the gastric and pancreatic gland concentrates employed in the hydrolysis of the basic food.

Panopepton is a bright, rather dense, deep amber-colored fluid, with a characteristic bouquet, grateful to the palate and stomachic. The finished product contains 24% of total dry solids.

Protein	6.50	
Carbohydrates	16.50	
Ash	1.	— 24.00

Panopepton is of a uniform standardized composition; it is highly agreeable; requires no preparation. It is a potent restorative and emergency food in serious straits; a fortunate recourse for the invalid.

Panopepton is a dynamic food.

Panopepton is most acceptable taken cold, undiluted.

The manufacturers of MONSOL confidently recommend these new TOILET PRODUCTS to members of the medical profession for personal use

The profession has already exhibited great confidence in the prophylactic value of Monsol Pastilles—many doctors find them the only convenient method of adequately disinfecting the mouth and throat. Now that we have Produced a new Monsol Dental Cream and Toilet Soap .....

MONSOL DENTAL CREAM 1/- per large tube

MONSOL TOILET SOAP 8d per tablet

... both modern products in the best sense of the term, and both containing a really effective proportion of Monsol, we have no hesitation in urging medical men to incorporate them in their toilet, as one of their routine measures against personal infection. Pleasant to use, and very mild, although of high germicidal value, these products afford further evidence of the unique properties of Monsol—the most powerful SAFE antiseptic.

Remarks ON SOME ASPECTS OF THE PROBLEM OF THE EPILEPSIES.*

BY

S. A. KINNIER WILSON, M.D., F.R.C.P.,

PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL FOR PARALYSED AND EPILEPTIC, QUEEN SQUARE.

IT is only five years since this Section of the British Medical Association, at the Bradford Meeting, was occupied with a discussion on the nature and treatment of epilepsy; and the fact that epileptic problems are again offered for consideration may properly be taken as proof of continuing interest in their examination and hope for their solution. Indeed, if we are to judge by recent output,[1] epilepsy and its allied conditions form for the moment one of the "growing points" of neurological research; and this is matter for congratulation, since nothing but good can emerge from a vigorous and concentrated attack on the difficulties presented by an age-old yet ever new and common morbid clinical state.

I am, however, personally under no delusion as to the complexities and intricacies of the subject, and I cannot conceive of any advantage in minimizing them; on the contrary, now is the time to remind ourselves of Curnow's dictum, often quoted by Hughlings Jackson: "The tendency to appear exact by disregarding the complexity of the factors is the old failing in our medical history." Were epilepsy not so involved a problem it would long ago have received at least a working interpretation, but the truth is the condition defeats us on many grounds; its etiology is heterogeneous, its semeiology indeterminate, its pathology dubious, its pathogenesis conjectural, and its therapeutics empirical. For the purposes of this discussion I can only single out one or two aspects to which attention may be usefully directed; they have been chosen intentionally as in my view best calculated to indicate the range of the problems connected with the epilepsies.

I. THE CLINICAL FEATURES OF EPILEPTIC STATES.

At the outset the student must face difficulties arising from the *clinical polymorphism* of epileptic phenomena. We all believe we can diagnose an epileptic fit with readiness when we see one, and it is true enough that a major attack is, fortunately, like nothing else in the whole field of symptomatology; but the epileptic state is not by any means confined to major seizures. Motor, sensory, psychical, and visceral variants exist; and in not a few instances it is hard to say whether the symptoms observed belong to the epileptic group. To separate recurring involuntary movements of a tic-like or spasm-like character from local epilepsy is often difficult, and sometimes impossible. Moreover, during a major attack the observer will frequently notice movements which will not bear interpretation as essentially convulsive; they are co-ordinated, and have the appearance of being purposive, involuntary though they must be. At the other end of the scale are fits distinguished by relative motionlessness—an akinetic or inhibitory variety that refuses to be separated from the main class by any physiological or clinical criterion, unless, indeed, our semeiological scheme is to be convicted of arbitrariness. But apart from the seizure itself we have to consider pre-seizure and post-seizure disorders, which are integral parts of the whole, however grossly they differ from the symptomatology of the attack of convulsive movement. It will therefore aid us in taking a large, a scientific, view of the question if we remember the following points.

1. The epileptic aura is a *sensation*, and thus a symptom belonging to the *psychical* series. It is something in consciousness. The wonderful historical study of the aura conducted long ago by Herpin[2] emphasizes the hallucinatory nature of this familiar phenomenon, for a description of which we are dependent on the patient himself. But I stress the fact that it need not be either distorted or caricatured; any sense may be involved, simply or elaborately; I mention in passing, as worthy of special remark, hallucinations of the muscular sense. Further, it may be more intricate still, consisting of a series of panoramic pictures, of forgotten memories recalled, of incidents apparently re-lived; and in this respect its relation to some of the phenomena we call "hysterical" is immediately apparent.

2. Interruption of the stream of *consciousness* may, or may not, accompany epileptic manifestations. Absolute unconsciousness may supervene without aura, fulminantly; but many fits, especially perhaps those of a local or unilateral, and some of a visceral kind, run their course with conservation of consciousness, enabling the subject to observe and comment on his own experiences.

3. The *motor content* of the fit consists usually of violent convulsive movements, not to be likened to any of everyday life—powerful repetitive muscular contractions at their wildest and most intense. Yet every clinician knows it is not always thus. Mild flickers of finger and thumb, quivering facial contractions round the mouth, repeated local twitching of a solitary limb-segment, something little more than the striking of an attitude in momentary spasm, can constitute the whole of the motor performance. We must note, again, the not infrequent occurrence of co-ordinated, quasi-purposive movement; and also absence of movement.

4. The *sensory elements* in an epileptic seizure, aura apart, sometimes make up practically the whole of it; further, in numerous instances the aura develops as though to herald the onset of the usual attack, without the latter making its appearance.

5. The *visceral components*, neurosympathetic in origin, are just as significant as the somatic, and just as frequent. Here are included circulatory, respiratory, vasomotor, vesical, rectal, renal, vagal, salivary, sudatory, pupillary, and other phenomena.

6. As for *post-seizure manifestations*, they embrace the most varied sets of opposites, from sleep to fugues, from stupor to aggressiveness and combativeness, from speedy or immediate recovery to prolonged headache, physical fatigue, and general malaise. In some of these respects they are completely indistinguishable from what occurs in the condition we still, for want of a better name, call hysteria.

With all this the clinician is familiar. My sole purpose in this sketch has been to underline that *heterogeneousness of manifestation*, ranging from the psychical to the visceral, which has to be included in any survey of epilepsy and has to be accounted for by any theory of pathogenesis.

II. THE INHERITANCE OF EPILEPSY.

Epileptic phenomena being demonstrably of extreme diversity, it becomes a question whether inheritance can be of any particular import in connexion therewith. Twenty-one years of practice and hospital experience have long since convinced me that the hereditary factor is persistently overrated, and the personal or constitutional factor underrated. The number of cases in which no hereditary element can be traced far exceeds that in which such a factor seems to be responsible. It is time protest should be unitedly voiced by neurologists against the portentous ascription of a sinister prognosis to every case of epilepsy because of a supposed inheritance and consequent incurability. Gowers[3] found a family history of epilepsy in about 27 per cent. of his own and other collected cases (2,400); and Russell Brain[4] in 28 per cent. of 200. But the percentage noted by other observers has been less still (in Spratling's series of 1,070 cases parental epilepsy existed in 16 per cent.; Davenport and Weeks,[5] 19; Binswanger,[6] 11). Even if we assume heredity for, say, 20 per cent., this means that in no less than 80 per cent. that factor is altogether awanting.

The matter can be approached from another angle. Were inheritance really a determinant, then in a large out-patient experience I should find myself treating many cases

* Made in opening a discussion in the Section of Neurology and Psychological Medicine at the Annual Meeting of the British Medical Association, Manchester, 1929.

of the condition among siblings. As a fact, this is distinctly rare. At the present time the sole *familial pair or* group is that of two epileptic sisters, whose family history is negative, and who are identical or homologous twins[7]—a striking example of the significance of the personal or constitutional component. Myerson[8] cites information obtained (1925) from the superintendent of the Massachusetts State Hospital for Epileptics to the effect that among 1,500 inmates only four families of 11 persons in all were to be found. At the same institution Thom[9] ascertained that 138 marriages of epileptics resulted in 553 offspring, among whom a history of epilepsy was obtainable in only 10 cases (1.8 per cent.). The most recent figures are those of Pilcz,[10] who traced 161 children of 144 epileptic mothers; 78 died under one year, and of the others five were imbecile, three criminal, four psychopathic, two psychotic, and *only three epileptic. It is, I submit, impossible* to draw any other conclusion from these statistics than that direct heredity is of little moment in comparison with other inducing factors.

III. The Experimental Production of Convulsions.

The first point of importance that emerges from a great number of researches, old and new, on the experimental production of epileptic fits is that normal animals can be *made to develop convulsions with ease and certainty.* No inheritance is requisite, nor does this consideration, I venture to say, ever cross the mind of the experimentalist. Whatever the provenance of his laboratory animals, they are all potentially capable of developing epilepsy.

Study of methods reveals two possibilities, or, rather, two main technical procedures for the production of the convulsive state, and these may be classed as (1) neural, and (2) humoral, respectively.

It is of some relevance, I consider, to note at once that these may act separately or interrelatedly. This has been well demonstrated by Dandy and Elman,[11] who, to begin with, provoked convulsions in a normal cat by simple oral administration of absinthe in sufficient quantity. They next made cerebral (pre-Rolandic) lesions in the animals employed by either cortical or subcortical extirpation or the introduction of a foreign body subcortically (all the lesions were unilateral). Within from one to five months such animals became much more sensitive to the effect of absinthe, one-third to one-seventh of the original dose now resulting in fits. The addition of a pathological cerebral factor increased the facility, and aggravated the degree, of action of the convulsant; in other words, cerebral injury lowered the convulsion threshold. Experimental provocation of fits in the human subject also has in recent years been given much attention, in regard to both epileptic patients and normal persons, and a considerable gain to knowledge has thereby accrued.

(1) Taking the humoral factor first, we may define it comprehensively as that component in the production of experimental (both laboratory and human) epilepsy which consists in alteration of body fluids and biochemical constituents either mechanically or in connexion with exogenous and endogenous noxae. The table below is based on those published by Brock[12] and by Lennox and Cobb[1], with some modification.

Table I.—*Humoral Factors.*

Mechanical.

1. Increased intracranial pressure.
2. Increased permeability of tissues.
3. Alteration of water balance; oedema.
4. Pressure on or ligation of carotids and vertebrals.

Exogenous.

1. Convulsants (alcohol, lead, acid fuchsin, camphor, absinthe, thujone, cocaine, picrotoxin, etc.).
2. Insulin hypoglycaemia.
3. Foreign proteins.
4. Anoxaemia (variously induced).
5. Alteration of acid-base equilibrium; alkalosis (variously induced).

Endogenous.

1. Disorder of endocrines (parathyroid, thyroid, pituitary, ovary, etc.).

Without examining in any detail the "convulsigenic" significance of these various factors, I shall for the purpose of this discussion content myself by setting forth certain general conclusions recently arrived at by Lennox and Cobb.[13]

1. Acidosis tends to inhibit, and alkalosis to augment, seizures.
2. An increased tension of oxygen in the tissues tends to inhibit and a decreased tension to augment seizures.
3. Oedema of the brain tends to increase, and dehydration to diminish, seizures.

Although these generalities merit attention the modes of action of the various factors have not been satisfactorily determined, and the separateness of their functions is not established. In other words, we are not in a position to say that the mechanical and the toxic components are always in essence contrasted or in their effect mutually and invariably independent. And not a few anomalies and difficulties remain for investigation. In order to produce opacity of cerebral arteries for radiographic purposes Moniz and Lima[14] have injected harmless solutions of sodium iodide into the internal carotid, transiently ligatured; and in "a large number of cases" this has been followed by severe and rapidly developed Jacksonian fits, involving the body and limbs *on the same side as the injection and ligation.* At present no satisfactory explanation of this apparent paradox is forthcoming. The experimentation of Temple Fay[15] appears to show that the mechanical factor (pressure, increased fluid, defective fluid absorption) is at least as significant in numerous instances as any of a chemical or biochemical nature (see further below).

(2) As for the second (neural) mechanism, it has been known for years that direct excitation of neural centres can result in the development of unilateral or generalized epileptic attacks. When in these days so much attention is being directed to humoral factors it is essential not to underestimate the importance of the other.

IV. The Occurrence of Convulsions in Pathological States.

If the deductions of the experimentalist in respect of epileptic determinants are to prove of *value they* must be capable of substantiation from the clinical side—that is to say, there must be evidence that these, or some or other of these, play a part in the production of epileptic syndromes under pathological circumstances. What, then, are the neural and humoral (or humori-vascular) conditions encountered in clinical medicine that are likely to exhibit epilepsy as one of their manifestations?

Taking neural (cerebral) conditions first, we recognize in what a large number of diverse organic cerebral states epilepsy in one or other form may make its appearance, and these can be tabulated as follows.

Table II.—*Organic Cerebral States associated with Epilepsy.*

1. Cerebral tumours, of diverse kinds and sites.
2. Cerebral infections and toxi-infections (varieties of encephalitis, syphilis, tuberculosis, abscess; toxins of many specific fevers and exanthems, etc.) (Some of these are classifiable as humoral states also.)
3. Cerebral toxi-degenerations or scleroses (disseminated sclerosis, tuberous sclerosis, Pick's cortical atrophy, Alzheimer's disease, diffuse sclerosis, Westphal's pseudo-sclerosis, etc.).
4. Cerebral trauma.
5. Certain varieties of congenital and heredo-familial disease.

In some organic cerebral affections fits are few and far between, and in the case of fevers and exanthems they often occur solely at the onset. In other instances they are frequent and persistent. If we seek a common factor for the development of convulsive attacks in these uncommonly diverse states it will be difficult to find, no doubt; but this question we shall for the moment postpone.

Passing now to humoral and vascular cerebral pathological conditions, we can classify them in the following way.

Table III.—*Humoral and Vascular Cerebral States associated with Epilepsy.*

1. Disease of blood vessels (thrombosis, embolism, haemorrhage, arterio-sclerosis, endarteritis obliterans, aneurysm, etc.).
2. Disorder of cerebral circulation (heart-block, anaemia, asphyxia of various origins, etc.).
3. Disorder of cerebro-spinal fluid regulation (hydrocephalus, external ("occult") hydrocephalus, alterations in fluid pressure, etc.).

Neither of these two latter tables makes any pretence at completeness; nor, for that matter, have I by any means exhausted the catalogue of clinical conditions, temporary or otherwise, in the course of which epilepsy may reveal itself, for I might mention its occurrence during the administration of anaesthetics, in association with narcolepsy, under the influence of emotion, in alternation with certain psychical conditions, such as attacks of bad temper, and so forth.

V. The Mechanism of Production of the Epileptic Seizure.

If now we put together the information garnered from the two preceding sections we shall probably not be far wrong in concluding that it can be summarized as implying the existence of three or four determinants, at most, for the production of epileptic phenomena.

An epileptic disorder is a disorder of a neuronic mechanism, without question; not of any specific mechanism, but simply of the individual's neural network in one or other of its parts. True, the major portion being motor, the disorder exteriorizes itself via the pyramidal system, but it commences anywhere, so to speak; witness the polymorphic aurae.

The crux of the pathogenic problem remains; is this neuronic disturbance (irritative or release, it matters not) initiated in the neuronic mechanism itself, or is the latter influenced by humoral or vascular change? Does one accompany the other, or precede? At the present time no direct answer can be given to the question. What evidence has accumulated is indirect and collateral, and may be set down as follows.

1. *Mechanical Determinant.*

It has for many years been suspected, and often argued, that some connexion exists between the epileptic state and increase in amount and pressure of cerebro-spinal fluid; and the view has often been expressed that a relation can be established between the occurrence of the latter and failure in fluid absorption owing to arachnitis or other pathological local condition. According to Dandy,[16] Fay,[15] Foerster,[17] and many more, *x*-ray photographs of the head in a large number of idiopathic epileptics (fluid being replaced by air for radiographical purposes) have shown the existence of enlarged subarachnoid spaces, more especially over the vertex and fronto-parietal regions, while, pathologically, subarachnoid collections of fluid, local oedemas, and such-like conditions have often been seen. These and other data suggest the possibility of external hydrocephalus—the "occult hydrocephalus" of Reynolds,[18] who has found the condition in epileptic subjects at operation—which arises from defective fluid absorption and leads to pressure, and so to fits. Fay[15] has recently added to our knowledge of this particular mechanism by his examination of the Pacchionian bodies in chronic epileptic brains. They are the portals through which the fluid in large part escapes, and it is therefore instructive to note that his colleague Dr. Winkelman has found various stages of sclerosis, calcification, atrophy, failure of development, and other abnormalities in these organs in epileptic subjects. Such changes follow infections, haemorrhages, local injuries, toxicoses, etc. They suffice to account for delay in fluid absorption, fluid accumulation, back pressure, and consequent supracortical oedema. Yet the problem still remains—to explain the occurrence of fits, given such pathological circumstances.

2. *Vascular Determinant.*

Many direct observations have been made of the vascular state of a patient on the threshold of an epileptic attack and of the exposed brain surface throughout an attack, and the consensus of opinion holds that cerebral and general pallor or anaemia is more or less constantly visible to the eye just as the seizure commences. This circulatory derangement or disorder is confirmed by the frequent observation of failure of the peripheral pulse at the outset, and the rarer one of constriction of retinal arteries at the same moment. These are old and long-established facts, which we owe to clinicians of other generations (Moxon,[19] Trousseau,[20] Hughlings Jackson, Hilton Fagge,[21] Broadbent[22]), whose work should not be overlooked by newcomers in the epileptic field. The analogy of these phenomena with what obtains in syncopal or fainting attacks is unmistakable, and was minutely studied by Russell[23] a number of years ago. In 1903 the circulatory steps were thus epitomized by Francis Hare[24]:

> 1. Vaso-constriction, causing rapid rise in general blood pressure.
> 2. Cardiac inhibition (vagal), to counteract the effects of the above, causing sudden fall in general blood pressure.
> 3. Sudden cerebral anaemia, causing unconsciousness and tonic spasm.
> 4. Recommencement of the heart beat, causing rise of pressure, returning cerebral circulation, relaxation of tonic spasm, and clonic convulsions.
> 5. Re-establishment of blood pressure and cerebral circulation; cessation of convulsions; sleep recuperative of exhaustion and damage.

It is undoubtedly possible to harmonize the facts of clinical observation and of experimental epilepsy with this sketch of the phases in pathogenesis; but there are many obscurities.

What is the proximate cause of the sudden initial vascular constriction? And where does it start? To the former question no satisfactory answer is as yet forthcoming. We do not know whether the vasomotor change begins in the vasomotor centre of the bulb, or locally in the cerebral cortex, or distally, by way of reflex influence on the medulla or cortex. And even when we assume for vaso-constriction a pathogenic significance, I may point out that by itself transient cerebral anaemia is insufficient to determine the epileptic attack. Elsewhere[25] I have commented on and criticized the evidence in its favour, and have endeavoured to show how indeterminate the relationship is. Changes in cerebral circulation accompany the march of events in an epileptic fit, but whether the interconnexion is causal remains to be proved. Were cerebral anaemia the *per se* cause, then every deathbed, more or less, should be the scene of convulsions, which is, fortunately for all concerned, not the case. Nor can the occurrence of an integral epileptic phenomenon—the aura—be thus easily explained, for it is in numerous instances a precise psychical activation, a hallucination; and there is no reason to imagine that neural activity is accompanied by anaemia in the cerebrum of the normal subject. If, however, we assume it to come into consciousness before cortical vaso-constriction, we still are faced with the enigma of how it arises itself, how it is related to the latter, and what is the state of affairs when it is not followed by convulsions. Is the existing condition then neural or vascular? I submit, further, that many local cerebral anaemias are unaccompanied by discharging phenomena (witness the flaccid palsies of embolism and thrombosis); and, on the other hand, that varieties of epileptic discharge occur in a way at once so limited and so continuous (some Jacksonian attacks, epilepsia partialis continua) that it seems impossible to conceive for them a vasomotor determinant such as is suggested for major fits.

In arguing thus I do not underrate the importance of the vascular factor, which can properly be made responsible for some of the obvious manifestations of the seizure, and I do not hold entirely with my former teacher, the late Sir William Gowers,[26] when he stated dogmatically that "The vasomotor theory of epilepsy is alike unneeded, unproved, and inadequate. The phenomena indicate that there is a discharge of grey matter, and there is nothing to warrant us in going beyond the grey matter concerned in our search for the origin of the discharge." But it is my present considered opinion that proof of the initiation of the whole sequence of events by a causal vasomotor constriction is lacking, and that it is equally conceivable that a neural factor originates the vascular change.

3. *Humoral Determinant.*

The humoral or physicochemical determinant has, as we have seen, received an immense amount of attention in recent times, and some conclusions have been outlined above. Briefly, it must be considered as established that a number of conditions (hyperventilation, injections of various chemical substances, anoxaemia variously produced)

cause experimentally a marked fall of O_2 tension in the tissues and are calculated to give rise to convulsions (Argyll Campbell[27]). And it is frequently stated that the "purpose" of convulsions is to counteract this O_2 deficiency. The relation of such deficiency to alkalosis and other non-neural components is sketched by Lennox and Cobb[13] as follows:

"Contraction of cerebral vessels might lead to a decrease in the oxygen supply to the brain. Because of the anoxaemia there would be dilatation of capillaries with passage of fluid outward through their walls. One or more of these factors—decreased oxygen tension, oedema, increase in intracranial pressure—might lead to abnormalities in the activity of cortical neurones and a fit. Consequent on the convulsion there would be an accumulation of carbon dioxide and lactic acid in the tissues, which would initiate a reversible reaction. Accompanying the acidosis there would be an increase in the utilization of oxygen by the tissues, a passage of fluid into the capillaries, and a restoration of normal intracranial circulation."

The clinician is willing to believe that such a series of physicochemical interchanges accompanies a major epileptic seizure; but he notes that the description commences with a postulated "contraction of cerebral vessels," which, as I have just emphasized, itself remains unexplained, of uncertain origin, and of dubious application to various clinical symptoms which cannot be expelled from the epileptic category. Lennox and Cobb, it is satisfactory to observe, are aware of the hiatus, for they admit that "these processes are only contributory; they may be effective only in persons with a tendency to seizures, and with those having some pathology either in the brain, the body, or the emotional life."

4. *Neuronic Determinant.*

We are therefore, after this excursus into newer fields of investigation, brought back, not unexpectedly, to the position which for some is still unassailed (I do not say unassailable)—namely, that the essence of all epileptic semeiology, major or minor, pre-seizure or post-seizure, psychical or visceral, is neuronic derangement, and that this derangement is of neuronic derivation. Nervous tissue can be, and is often enough, influenced by mechanical, vascular, and humoral agencies; but the secret of epilepsy—the core of the problem—resides in the qualities of the neural mechanisms exhibiting discharge.

It is wise not in the least to undervalue the importance of recent acquisitions to knowledge, apropos vascular and humoral constituents and accompaniments of epileptic fits, but at the same time the following considerations must be given due weight.

1. The action of laboratory convulsants such as absinthe, which will produce fits in a normal animal, is much facilitated if the animal undergoes any cerebral injury.

2. Single humoral or vascular factors, by themselves, are often insufficient to produce fits; and even when combinations occur there may be no element of essential repetitiveness in the attacks thus generated.

3. Only a small percentage, as is well recognized, of cases with head injuries and with histories of infective and other conditions, leading presumably to the pathological states mentioned above, react with fits.

4. The development of epilepsy in some organic brain states (see especially No. 3 in Table II above) pleads in favour of a neural factor, seeing that no evidence of vascular or humoral anomalies is forthcoming in them.

5. A "susceptibility" or "tendency" can scarcely be ruled out in cases of direct heredity and of epilepsy in homologous twins, and it is at least as easy to express this in terms of neural instability as of extraneural abnormality.

6. The clinical occurrence of so-called reflex epilepsy strongly suggests a pure neural reaction.

7. Certain features of the epileptic state are clinically indistinguishable from hysterical manifestations; but for the latter, so far as I am aware, no attribution to mechanical, vascular, or humoral precipitants is thought of.

8. Certain phenomena of the epileptic fit (for example, inhibition and radiation) are much more readily explicable by neural than by any extraneural mechanism.

It is therefore impossible to find one single common factor for the totality of epileptic manifestations, unless the significance of some inherent nervous factor, some functional propensity, is allowed. However unsatisfactory the word "tendency" or "instability" may be, however useful in cloaking ignorance, I do not consider this a feeble conclusion; on the contrary, it is consonant with the facts of observation; the only trouble is that we cannot at present gauge "susceptibility" by reference to objective criteria. Nor, for that matter, can anyone estimate what is signified by susceptibility to infection or illness of any kind, unless by rather vague allusions to "immunity." But the question of immunity in epilepsy has never yet been seriously approached. For this reason I shall conclude by a brief note on the influence of intercurrent conditions on the epileptic state.

VI. The Influence on Epileptic Semeiology of Other Intercurrent Affections.

This perhaps deserves more attention than has hitherto been accorded it. The observation is as old as the days of Hippocrates, for that Father of Medicine stated it himself, that intermittent fever replaced or mitigated epilepsy, whence the adage "Quartana epilepsiae vindex appellatur." Lenoir[28] (1901) remarked that Esquirol had commented on the diminution or disappearance of epileptic attacks during "accidents fébriles," while Hammond[29] in the same year said that some authors, struck with the favourable influence exerted by infectious diseases over a pre-existing epilepsy, had advocated "the establishment of some of these different processes, such as malaria and erysipelas, to cure it." As long ago as 1882 it was noticed by Bourneville and Bonnaire[30] during an epidemic of measles in epileptics and idiots at Bicêtre that while the intercurrent affection lasted fits were much decreased in force and frequency, and similar observations were recorded by Séglas[31] (at the Salpêtrière). Gowers[3] quotes the case of a child ("with strong inheritance") who suffered from fits from 2 years of age till 7, when they ceased during an attack of typhoid fever and did not recur till the age of 27. He also states that scarlet fever provides an exception to this perhaps general rule. Aldren Turner,[32] on the other hand, has seen a case in which a mild attack of scarlatina induced a period of amelioration lasting for several months; and another in which respite was obtained for a similar period after acute pneumonia. Bourneville,[33] once more, found during a typhoid epidemic among epileptic children (six cases out of seven) that the attacks were suspended while the pyrexia lasted, and that the improvement persisted for some time after recovery.

In my own experience measles and chicken-pox are the febrile illnesses which have sometimes effected a striking cessation of fits—nor has the improvement been limited solely by the duration of the intercurrent state.

So far as I have discovered no attempt has been made by Gowers or any of the other authors mentioned to explain the way in which this influence may be, theoretically, exerted. According to Francis Hare,[34] however, it is the pyrexia which is of significance, for it involves general vascular relaxation, and he argues that vaso-dilatation is similarly of value in cutting short attacks of both asthma and migraine. He quotes in this connexion Garrod, who noticed the effect of acute pyrexial gout on recurrent epilepsy.

"A gentleman had suffered from epilepsy from the age of 20 to 52; the fits were frequent, sometimes occurring as often as once a week. He then had distinct articular gout in one great toe, and afterwards experienced attacks of the same kind, from time to time, up to his death at the age of 72. From the first manifestation of decided gout there was an entire cessation of the epileptic convulsions."

It would be simple and proper enough to account for this particular ameliorating action on humoral lines; but in the case of the exanthems I scarcely feel that pyrexial vaso-dilatation covers the whole pathogenesis, just as I do not feel confident that the old observation that in children various acute diseases commence with convulsions, but in adults with rigors is to be elucidated by a theory of vaso-constriction, acting more precipitately in the former than in the latter.

Whatever the explanation, it may yet turn out to be of importance from a pathogenic and a therapeutic standpoint that epileptic manifestations are sometimes controlled by Nature's own methods.

TUBERCULOSIS OF THE LARYNX.*

BY

WALTER G. HOWARTH, M.B., B.Ch., F.R.C.S.,

SURGEON TO THE THROAT DEPARTMENT, ST. THOMAS'S HOSPITAL.

With so large a subject as this it is not easy to know from what side to approach it, and I think that it will probably best serve the purposes of the discussion which is to follow if I make a few remarks from a very general point of view, and let those that follow amplify or criticize some aspect that may particularly appeal to them.

I am afraid that, in spite of the fact that for the past twenty years I have tried to study this disease at St. Thomas's Hospital, the Victoria Park Chest Hospital, and elsewhere, I have really nothing to say that is new, and the more cases that one sees the more is one inclined to wonder at the protean manifestations of this disease as far as the larynx is concerned. If one examines carefully the larynx in patients who are suffering from pulmonary tuberculosis, one may say that somewhere about 10 per cent. show abnormality in the larynx. I do not wish to imply that a definitely recognizable tuberculous lesion is present in all these cases, but that the larynx is not quite normal; it may be that the mucosa is more anaemic than is usual, or there may be a generalized erythema, or possibly some fullness in the interarytenoid region. Do such departures from the normal occurring in a phthisical subject possess more than usual significance, and is there such a thing as a pretuberculous stage of the disease? I believe that many people consider that there is such a stage. Personally I am disinclined to admit this designation, and I would prefer to regard the local anaemia as a part of a more general one, and the catarrhal laryngitis as a not unusual accompaniment of the chronic cough, while the passage of sputum over the interarytenoid fold is surely sufficient to cause a little local hypertrophy without this being of necessity due to a definite tuberculous infection. At the same time, it is naturally advisable to keep a careful watch on such local conditions as they arise, and to make certain that they yield to the appropriate treatment.

What proportion of cases of proved phthisis exhibit laryngeal symptoms that are definitely tuberculous? The answer to this question is not very easy, as statistics are not by any means unanimous on the subject, and, like all statistics, they may be essentially fallacious, as often the information is not given as to what particular class of case is being dealt with. Thus at a large sanatorium (Midhurst) 8 per cent. show definite laryngeal disease, whilst at an institution such as the Victoria Park Chest Hospital, where the cases are year by year more carefully selected, the proportion may fall as low as 4 per cent. On the other hand, some recent American statistics from a State sanatorium mention 25 per cent. of laryngeal cases. However much statistics vary, it is, I believe, true to say that laryngeal complications of phthisis are certainly less common than they were even twenty-five years ago. Then, the average statistics of many skilled observers in Germany and elsewhere showed considerably more than 30 per cent. This improvement is, I think, undoubtedly due to the fact that the chest disease is recognized earlier and is usually treated most efficiently from the beginning of the disease.

It may be noted that I am assuming that tuberculosis of the larynx is secondary to pulmonary disease. This is, I think, almost universally agreed for the vast majority of cases, even though no definite lesion can be demonstrated in the lungs. There is to my mind, however, one lesion that is difficult to explain on this assumption, and that is the tiny nodule which may occur on the edge of a vocal cord in an elderly person, and which may give rise to the suspicion of cancer, but which the microscope proves to be tuberculous in spite of the fact that there was no trace of tuberculosis to be found elsewhere. I can recall at least two cases in which (with the concurrence of distinguished colleagues) I removed the supposedly cancerous cord with completely successful results, and no further manifestation of tuberculosis over a period of twelve years and seven years respectively.

When the larynx becomes affected in a case of pulmonary tuberculosis, how does the infection occur, and what parts are most commonly involved? In the large majority of cases secretion coughed up from the lungs produces a surface infection of the laryngeal mucosa, and the infecting bacilli can undoubtedly enter apparently intact epithelium, and still more so epithelium damaged by previous disease. When one considers the amount of sticky sputum that so often hangs about the interarytenoid region and the posterior ends of the vocal cords, it is perhaps surprising that infection does not more often take place. Certainly this stagnation of secretion in the region of the posterior commissure can be regarded as a very potent source of infection. In this connexion it is interesting to note that singers and some other voice users who do not tolerate any accumulation of mucus in the larynx are said to be less susceptible to laryngeal complications. This may be so, but there are, of course, other explanations.

When we allow the possibility of entry of bacilli through intact or abraded epithelium, or through the ducts of racemose glands, it seems perhaps unnecessary to consider the blood stream as the primary vehicle for the submucous deposit, and it may, indeed, be doubted whether infection ever occurs this way. At the same time, when once tuberculous disease has been established, spread to neighbouring parts of the larynx may undoubtedly occur by extension through the lymphatics.

It is, I think, agreed that in the majority of cases the posterior part of the larynx is most commonly affected, and it is here that we are accustomed to look for the earliest signs of disease. We are all familiar with the firm nodular

* Read in opening a discussion at a joint meeting of the Sections of Oto-Rhino-Laryngology and Tuberculosis at the Annual Meeting of the British Medical Association, Manchester, 1929.

infiltration, the feathery outgrowths, the regular cone-shaped palisade, or the round frog-spawn-like excrescences that are so often seen in the early stages, but it is well to remember that it is when the situation is unusual that the diagnosis is more difficult, and it would, in my view, be helpful if some of the many careful observers amongst us would tell us of some unusual appearance that experience has taught them to regard as significant. For my own part I have often thought that a curious, gelatinous-like appearance of one vocal cord merited very careful attention, whilst on several occasions a diffuse subglottic infiltration, only caught sight of when the cords are widely abducted, has seemed to be the starting point of the laryngeal disease. But the manifestations are so various that one is often forced to say: "I have never seen anything quite like this before, but it must be tubercle."

It is to my mind remarkable how many of the unusual conditions that one sees in the larynx turn out in the end to be tuberculous. It will scarcely be necessary for me to make more than a brief reference to the symptoms of this disease. They are of two types, and these depend on whether it is the interior of the larynx, or whether it is the structures at the entrance to the larynx, that are affected. It may, however, be well to say that as far as the intralaryngeal type is concerned, long before any definite hoarseness may be present, we may notice, or should notice, any slight alteration in the voice, such as tiring very easily, occasional huskiness, or loss of euphony, and any abnormal sensations in the throat or larynx such as a feeling of great dryness, irritation of a tickling or scratching nature, excess of mucus, and tendency continually to clear the throat. Any of these symptoms should, I suggest, call for a careful laryngeal examination, if such is not indeed part of a routine measure. Diagnosis of any laryngeal involvement in an early stage makes the outlook so much more hopeful.

I should like to turn attention to the question of treatment. Each year it is being more appreciated that the disease, serious though it undoubtedly is, is not really as hopeless as it is so often represented to be, and that indeed a considerable proportion of cases can definitely be cured, particularly if treatment is instituted at an early stage.

This treatment should, of course, be both general and local. The general treatment should, wherever possible, take place in a sanatorium, or under sanatorium conditions, so that every variation in the lung condition and the general health and resistance of the patient may be carefully watched, for upon the skilful care of the pulmonary disease depends the whole outlook of the patient. It has happened before now that the laryngeal condition has been healed but that the patient has succumbed to the pulmonary disease. In mentioning general treatment it would be well to ensure that there are no gross inflammatory conditions of the upper respiratory tract that might keep up irritation and delay the success of other therapeutic measures.

The question of local treatment has undergone many and various changes during the past twenty-five years, and even now constant experiment is taking place with local applications in the hope of checking the disease and mitigating its more distressing symptoms. From this multiplicity of endeavour two landmarks seem to me to stand out pre-eminently as definite advances. The first is the appreciation of the value of absolute vocal rest, and the second is the substitution of the galvano-cautery for other active surgical treatment. I am not quite certain who it was who first thought of silence as a means of ensuring physiological rest to the diseased larynx, but I know that in this country one of its earliest and most persistent advocates was Sir StClair Thomson, and he must be gratified to find it now regarded as the keystone in the arch of our local treatment.

It is remarkable what extensive lesions heal up under this treatment alone, always provided that the lung condition is favourable and that the patient co-operates to make the silence as absolute as possible. It will be necessary in the majority of cases to ensure that this treatment is carried out for six months or more, and this naturally puts a great strain on the fortitude of the patient. It will often be noted that for the first month or two little or no improvement is shown, and indeed the larynx may look definitely worse; but suddenly it begins to mend, and from that time progress is steady until complete healing has occurred. It is advisable that the larynx should be inspected once a month and the patient informed of the progress and encouraged to continue the vocal rest.

The surgical treatment of local lesions, mainly introduced by Heryng and Krause and advocated in this country by Richard Lake, consists mainly in the removal of infiltrated tissues and the curetting of ulcerated areas with the subsequent rubbing in of lactic acid and other mild caustics. These procedures marked a definite advance and many cases were undoubtedly cured by them; but to-day our Heryng curettes, epiglottis shears, and arytenoid punch forceps are seldom used, as their work can be more effectively performed by the galvano-cautery. The value of galvano-caustic puncture in suitable cases is, I am glad to say, gaining greater recognition, and is, as time goes on, likely to supersede all other procedures in the surgical treatment of local lesions. This method, valuable though it undoubtedly is, should not be used indiscriminately, and the cases in which it is proposed to apply it should be most carefully selected, not only with regard to the extent and situation of the local lesion, but also with careful consideration of the lung condition and the general resistance of the patient. In properly selected cases even a few applications at three-weekly or monthly intervals may restore an infiltrated arytenoid to normal or promote the healing of a definite ulcer. The galvano-cautery acts as a powerful counter-irritant, and it is the hyperaemia that is induced and the formation of granulation tissue with the development of new blood vessels that causes revitalization of the tissues and the healing of the tubercle, rather than any actual destruction of diseased tissue that may be achieved.

My experience of the use of direct sunlight is somewhat limited; it is difficult to be certain of it in this country, and I have never used it to the exclusion of other forms of treatment, so that its individual value is difficult to assess. One is certainly struck by the fact that the laryngeal mucosa is extremely sensitive to reflected sunlight, so that the applications and dosage should be under the strictest control. One of my patients was so pleased at seeing his own larynx with one of these cleverly reflecting appliances, designed, I think, by a Frenchman, that he was constantly sunning it, with anything but beneficial results.

Artificial sunlight has been strongly advocated by Wessely and others, and ingenious machines have been devised for its application. The dosage can be carefully regulated, but the treatment is apt to be a lengthy one, and of the cases that I have seen under treatment in foreign clinics some would probably have been cured more quickly by other methods.

It is commonly supposed that tracheotomy is only justified in this disease when laryngeal obstruction becomes severe, and that it should not be employed for the sole purpose of putting the larynx at rest. I am amongst those who consider that in some cases tracheotomy is not only justifiable but advisable. These cases are few and far between, and are mainly those in which there is an indolent, almost lupoid, infiltration, and where the lung condition is fibroid or inactive. Such cases, slowly progressive under other forms of treatment, may gradually yield to the complete functional rest that tracheotomy ensures.

For the cases that cannot be cured by the measures I have outlined treatment must unfortunately be mainly symptomatic, and it is in this field that experiment and ingenuity may devise methods and applications that may give considerable relief to the symptoms and amelioration of the laryngeal condition.

The chief symptoms that we have to contest are pain and cough. The relief of pain taxes all our resources, and every form of spray and insufflation may be called in to relieve the pain in swallowing that is so inimical to the general nutrition.

It was hoped that nerve-blocking would provide a means of efficiently controlling painful dysphagia, and in some cases it certainly is of value, but on the whole it has in

my hands proved rather disappointing, and it seems to fail most often in advanced cases in which one was hoping the most from it.

Cocainization of the spheno-palatine ganglion, as in the Sluder operation for ethmoidal disease, is said to abolish the reflex pain in the ear, but the effects are naturally only transitory.

Cough, which may be due to the local laryngeal condition, is often most satisfactorily relieved by the intratracheal injection of oily solutions. A large variety of drugs have naturally been employed, but a 3 per cent. solution of creosote in olive oil will be found to be as effective as any in relieving the irritation that seems to produce the cough.

There is one oily solution for local application that has within recent years been strongly advocated in America, but of which my experience is so limited that I cannot speak with any degree of first-hand knowledge. I refer to chaulmoogra oil. This appears to have a definitely beneficial effect not only as regards the diminishing of the irritable cough, but it is said also to allay the painful dysphagia very considerably, besides promoting the healing of ulceration in the larynx. The oil is rather a viscous one, and I have had it made up with two parts of almond oil so that it can be readily dropped into the larynx from a laryngeal syringe. If even a part of the benefits that are claimed for it can be substantiated after an extended trial it should certainly prove a most valuable addition to the medical side of our treatment.

It is in the later stages of the disease that the symptoms are so distressing, and anything that can give even temporary relief is well worthy of a trial. It is to be hoped that this discussion may reveal methods that are helpful and so carry us on the way to the attainment of our object.

TUBERCULOSIS OF THE LARYNX.*

BY

SIR STCLAIR THOMSON, M.D.,
F.R.C.P., F.R.C.S.

On a rough average one out of every three patients with active pulmonary tuberculosis suffers from the complication of a laryngeal lesion. In England to-day there are 55,000 individuals who require our knowledge and care to relieve and, if possible, cure them of this condition. Tuberculosis is not the most killing of the diseases we have to combat. Heart disease still heads the list. Pneumonia and bronchitis, together, hurry more people to the grave than does tuberculosis. But when we remember that tuberculosis attacks mankind chiefly when in the prime of life, that a third of all deaths between 15 and 40 are due to it, and when we recall the long and weary and expensive passage to the grave it may entail, we must congratulate the officers of these two Sections on taking this opportunity for focusing attention on what is the most serious complication of tuberculosis, next to meningitis.

Much encouragement lies in the well-established proof that tuberculosis is becoming both less frequent and less virulent. My own impression—which I hope to verify—is that the lessened virulence of the disease is shown by a diminution in the frequency with which the larynx is involved.

Five years ago I published the results of ten years spent in observing 477 cases of laryngeal disease discovered in 2,541 tuberculous patients, all of whom I had examined.[1] With your permission I will use these published figures for a few observations, as more extended experience has only served to confirm the conclusions I have already published as regards sex distribution, incidence of the disease, principles of treatment, prospect of cure, and so forth.

(These various points were then elucidated by a lantern demonstration.)

The principal conclusions are as follows:

1. Tuberculosis is found in about 18 per cent. of the patients admitted to a sanatorium.
2. It only occurs in 4.8 per cent. of patients in the early stage of pulmonary tuberculosis (Group 1 of the Turban-Gerhardt classification). Hence
3. The great importance of early diagnosis.
4. The post-mortem room shows that in advanced cases the larynx may be affected in half the patients who die of pulmonary tuberculosis.
5. The presence of a laryngeal complication darkens the prognosis at all stages. If we study their after-history, 60 per cent. of patients who left the sanatorium with a healthy larynx are alive when only 30 per cent. of those with a diseased larynx are still surviving after the same lapse of time. In other words, amidst laryngeal cases two are dead out of every three when, amidst larynx-free cases, only one has died.
6. No laryngeal case can be looked on as "slight." Its import is always serious, both as regards length of treatment required and ultimate recovery.
7. Seventy per cent. of only fairly favourable cases are dead.
8. In only too many cases which come under observation the prospect of recovery is so slight that it may be unjustifiable to submit the sufferer to any trying, dangerous, or expensive treatment.
9. On the other hand, a complete repair of the larynx has been obtained in no less than 25 per cent. of patients with tuberculous laryngitis.
10. Amongst 477 cases 119 cures have been obtained by sanatorium treatment, combined with silence, whispers, and the galvano-cautery. To secure both results—and to forestall the development of this serious complication—we only require earlier diagnosis and more prompt sanatorium treatment.
11. When we recall that Morell Mackenzie wrote that "it is not certain that any cases ever recover," we may derive much encouragement from the results.

Hippocrates said that no head injury was so slight that it should be neglected, and none so grave but that it might recover. No laryngeal lesion in tuberculosis is so slight as to be neglected; some serious ones may recover; but the majority of advanced cases are hopeless.

In such a kaleidoscopic disease as tuberculosis it is rash to commit oneself to too definite conclusions. In formulating these opinions time has prevented me from inserting many saving clauses and from dwelling on the relation of the laryngeal lesion and the primary focus to the general infection and to the local and general resistance.

PELLAGRA AMONG THE MAIZE-EATING NATIVES OF THE UNION OF SOUTH AFRICA.

BY

E. H. CLUVER, M.A., M.D., D.P.H.,
ASSISTANT HEALTH OFFICER FOR THE UNION OF SOUTH AFRICA.

In spite of the fact that maize, or mealies, forms the chief article of diet of the Bantu population of the Union, often to the exclusion of all else, pellagra outbreaks have been of relatively infrequent occurrence. Only three outbreaks of any importance are known to have occurred—one in 1906, when some 150 pellagrins were found among Zulu rebel prisoners; another in 1912–13, in the Pretoria Mental Institution, affecting about 60 native inmates; and the recent outbreak in the Durban prison command, in which a total of 64 cases have been reported to date among the non-European prisoners. In addition to these outbreaks sporadic cases have been reported, amounting to about 50, mainly from Natal (including Zululand) and the Transkeian native territory of the Cape Province. Only six of these patients were Europeans, the remainder being Eurafricans, Indians, or Bantus, the last-named greatly preponderating.

The relatively small amount of pellagra among our maize-eating natives is probably due to crude methods of grinding, which do not result in the removal of pellagra-preventing properties of the grain. The native merely stamps the grain, generally in a crude stone mortar.

In Table I all the known cases that have occurred in the territory now constituting the Union are summarized.

Table I.—*Known Cases of Pellagra that have Occurred in the Territory now Constituting the Union.*

Year.	Number.	Race.	Region.	Remarks.
1906	150	Native	Zululand	Dinizulu-Bambata rebellion.
1907	Several	Native	Zululand	From Tugela Valley; seen by Dr Knight.[2]
1912	1	Native	Durban	Reported by Dr. Drummond.
1912-13	60	Native	Pretoria	Mental institution.[1]
1913	Several	Native	East London	Gaol.[3]
1913	1	Native	Transkei	Reported by Dr. Mitchell.
1914	1	Coloured	East London	Gaol.
1916	1	Coloured	East London	Gaol.
1920	1	European	Durban	Reported by Dr. Drummond
1922	1	European	Durban	Reported by Dr. Drummond.
1922	4	European	Witwatersrand	Reported by Dr. Pyper.[5]
1927	1	European	Witwatersrand	Reported by Dr. Orenstein.
1927	1	Native	Witwatersrand	Reported by Dr. Orenstein.
1927	1	Native	Amatikulu	Reported by Drs. P. Ross and Rhodes.
1927	3	Native	Durban	Addington Hospital.
1927-28	64	Native	Durban	Prison Command.
1928	7	Native	Durban	Addington Hospital.
1928	1	Native	Witwatersrand	Krugersdorp Gaol.
1928	1	Native	Queenstown	Municipal location.

During the Zulu rebellion of 1906 Dr. L. G. Haydon was in medical charge of 3,000 prisoners, from among whom he picked out some 150 individuals exhibiting symptoms which, from his description, leave little doubt that the patients were pellagrins. A photograph of one of them, showing typical and unusually extensive erythema of the forearms, is preserved in the records of the Union Health Department. These prisoners had by force of circumstances been detained under bad conditions for a considerable time in Zululand. They had been confined in batches in wire enclosures with unsatisfactory food, chiefly mealies. It is also probable, remarks Dr. Haydon, that during the progress of the rebellion the majority of the native rebels in the field had had to subsist entirely on inferior mealies.

The outbreak in the Pretoria Mental Institution commenced in 1912 and extended into 1913. Some 60 of the native inmates, chiefly males, were affected. The patients showed the typical rash; diarrhoea and neuritis were prominent features. The intensity of the disease varied greatly; many of the cases were very severe, and about 15 were fatal. When the condition was recognized as pellagra the diet was immediately improved, chiefly by the addition of peanuts and extra green vegetables, with a view to increasing the fat and vitamin content of the ration. Soon after this improved diet scale had been introduced the outbreak ended.

In 1913 Dr. J. Drummond[2] described what he considered to be the first recorded case in Natal. This was a native pellagrin admitted to the Addington Hospital, Durban, in December, 1912. In his paper Dr. Drummond states that the condition, though not previously recorded in Natal, had been noted as present among the coloured lunatics at the Robben Island Mental Hospital, Cape. This reference appears to be erroneous; investigation of the records does not confirm it. In the discussion[2] on Dr. Drummond's paper, Dr. Knight stated that in 1907, when in the Nqutu district of Zululand, he had reported a series of cases which conformed closely to the one described; the patients had all come from the Tugela Valley, and had all died.

In August, 1913, Dr. Barcroft Anderson, district surgeon of East London, reported that he had several cases of skin diseases among native women in the East London gaol which he believed to be pellagra. He investigated the fly population of a neighbouring stream, Sambon's simulium theory at that time holding the field. The specimens he sent in were found, however, not to belong to the genus Simulium. A photograph of a typical case was taken by Dr. Barcroft Anderson and published in the *South African Medical Record* of October 25th, 1913.[3]

Dr. J. A. Mitchell saw a case in December, 1913.[4] The patient was a native convict from the Transkei. He was arrested in April, 1911, at Cathcart, removed the following month to East London gaol, and in November, 1913, to Tokai, where he was seen by Dr. Mitchell, whose diagnosis of pellagra was confirmed by the Government pathologist.

Cases of pellagra in coloured female convicts in East London were reported by Dr. Barcroft Anderson, one in 1914, another in 1916. Dr. Drummond reported a European case in Durban in 1920. He then made a general inquiry throughout the Union, but could trace no other cases. In 1922 he saw a case in a European female who had contracted the disease in Newcastle, Natal; she died in Durban Sanatorium. He saw two more cases in 1916—one a European, the other a native. Writing in the *South African Medical Record* of July, 1922, Dr. C. Pyper mentions having seen four cases in Europeans in Johannesburg which he diagnosed as pellagra.[5]

In April, 1927, a leprosy board consisting of Dr. Park Ross (assistant health officer for the Union) and Dr. Rhodes (Government pathologist) diagnosed pellagra in a native who had been sent with a diagnosis of leprosy to the leper institution at Amatikulu, Zululand. During 1927 the superintendent of sanitation, Rand Mines, Ltd., made careful inquiries as to the possible occurrence of pellagra on the Witwatersrand mines. He could trace only two cases—one European, the other native. In the Durban prisons outbreak, which extended from December, 1927, to December, 1928, 64 native cases occurred. This outbreak will be dealt with in greater detail.

During February, 1928, a circular was sent by the Union Health Department to all district surgeons in attendance on prisoners, asking for reports of any cases of pellagra that had been encountered in either their prison or private practice. Nineteen district surgeons reported that they had not seen any cases; two had seen a single case each—one in Krugersdorp, Transvaal, the other in Queenstown, Cape. Both patients were natives.

Seven cases in no wise connected with the Durban prisons outbreak were admitted to Addington Hospital, Durban, during 1928. One of these patients, a Zulu, when interviewed, stated that he had come south from Zululand with the express purpose of being admitted into a Government hospital to be treated for his condition. He stated that he had seen many natives in Zululand with skin condition similar to his, and he persisted in this statement when severely cross-questioned.

There can be little doubt that pellagra is more common in the Union, especially in the native territories of Zululand and Transkei, than the data given above would suggest. Its diagnosis may easily be missed by those not familiar with its symptoms.

The Outbreak in the Durban Prison Command.

During the period December, 1927, to December, 1928, 64 cases occurred among non-Europeans in the Durban prison command. The first case was seen by Dr. Rhodes on December 22nd, 1927. With the exception of this first case, detailed information, collected chiefly by Dr. G. D. English, assistant district surgeon, Durban, is available.

Date of Onset.—Of the 63 pellagrins of whom detailed information is available, only 2 showed symptoms on admission to gaol; in 25 symptoms appeared within three months of admission; 10 had been in prison three to six months; 8 six to twelve months; 5 one to two years; 13 over two years.

Prison Diet Scales.—Six diet scales are used in the prisons throughout the Union. The diet varies according as to whether the prisoner is European, coloured (that is, Asiatic or Eurafrican), or native, and whether he is serving a sentence of three months or less (short sentence), or one of over three months (long sentence). The scales are officially known as:

Diet A.—Short service European prisoners.
Diet B.—Long service European prisoners.
Diet C.—Short service coloured prisoners.
Diet D.—Long service coloured prisoners.
Diet E.—Short service native prisoners.
Diet F.—Long service native prisoners.

Of the 63 patients, 2 had been on C diet, 7 on D, 10 on E, 36 on F, and 8 on E and F. All the official non-European diets are physiologically deficient. They are analysed in Table IV.

TABLE IV.—*Non-European Prison Diet Scales of the Union of South Africa.*

DIET C.—Short Service Asiatic and Eurafrican Prisoners.

Article of Diet.	Weekly Ration in oz.	Daily Ration in oz.	Daily Protein in oz.	Daily Carbohydrate in oz.	Fat in oz.	Calories.
Mealie meal	70	10	0.75	6.6	0.43	255 625

Beans	48	6.88	1.58	4.12	0.10	752.73
Total daily ration			4.16	22.735–21.735	2.695–1.695	3,622 58–3,688.83

"E" diet is seen to be grossly deficient in calorific value and deficient also in protein, fat, and carbohydrate. The "F" diet has a reasonably high calorie value, but this is obtained by an overbalance of carbohydrate; fats are deficient and the proteins of low biologic value. None of the diets make adequate vitaminic provision; no uncooked food is provided; the main source of vitamin is the vegetable ration.

The first six cases which occurred in December, 1927, were short service natives on "E" diet. As the result of representations from the Union Health Department, all native prisoners in the Durban prison command were put on the more liberal "F" diet on April 1st, 1928. During the three following winter months only two cases occurred; but during the remaining five months of the year eighteen more cases occurred. From the fact that cases continued to occur after the discontinuance of "E" diet the director of prisons deduced that the fault did not lie in the insufficiency of this scale, and he suggested that it be reverted to. He pointed out that his department was accused from time to time of overfeeding its prisoners and of making prison conditions too comfortable. The position is indeed difficult, as the prisoners have often subsisted on a pellagra-producing diet previous to conviction. Even the deficient prison diet may therefore be attractive, and much of the deterrent effect of prison life may be lost. The director of prisons also pointed out that, though the existing diet scales had been in force throughout the Union prisons for the past seventeen years, there had been no previous outbreaks of pellagra. He was apparently unaware of the cases which occurred in East London gaol in 1913, 1914, and 1916.

Nature of Work and Degree of Exposure.—The Durban prison command consists of three sections: the Central Gaol, the Point Prison, and the Congella Prison. The population of the Central Gaol consists of European and non-European males and females. The two prisons house non-European males only, and chiefly long sentence prisoners. The non-Europeans in the Central Gaol are chiefly short sentence prisoners. Another important difference between the gaol and the prisons is the nature of the work. The prisoners from Congella and Point Prisons work mostly on harbour construction in the open, and are much exposed to the rays of the sun; those from the gaol work chiefly in the shade. Exposure to the sunlight is known to be a contributory cause of pellagra, especially when associated with hard work. Other things being equal, one would therefore expect to find more pellagra cases from Point and Congella than from the Central Gaol. The only special feature favouring the production of pellagra in the Central Gaol was the preponderance of short service native

prisoners who, until March 31st, were on the grossly deficient "E" diet. The preponderance of cases among the prisoners working chiefly in the sun is indicated in the following table. The two cases found suffering from pellagra on admission are omitted from the table.

Table V.—*Distribution of Pellagra Cases in the Three Sections of the Durban Prison Command.*

	Central Gaol.	Point Prison.	Congella Prison.
Average daily number of non-European inmates	698	505	405
No. of cases of pellagra	13	17	33
Percentage	1.9	3.4	8.2

Of the 13 cases which occurred in the Central Gaol, 10 occurred previous to the introduction of diet "F" for short sentence prisoners.

Etiology.

There is now fairly general agreement that pellagra is the result of dietetic deficiency. A pellagra-preventing dietary is necessary to prevent its occurrence. This pellagra-preventing property is possessed by most natural foods with the exception of oils and fats. It is stated to be located in a vitamin which has been named "P-P," and is believed to be the same as the vitamin necessary for the prevention of the occurrence of the canine disease known by American veterinarians as blacktongue.[6] The "P-P" content of foods has not yet been worked out with the same degree of accuracy as in the case of the other vitamins. It is probably present in all vegetables and fruit in small amount. In "P-P" value Goldberger equates 2 lb. of tomatoes, a quart of buttermilk, 1/2 lb. of lean meat, and 1 oz. of powdered yeast.[7] Maize (mealies) was found to contain very little, if any, of the preventive for both blacktongue and pellagra.[8]

The pellagra-preventing vitamin appears to be identical with vitamin B2, which has a somewhat similar distribution among foodstuffs as vitamin B, now referred to as vitamin B1. If the neuritic symptoms which result in rats from deprivation of vitamin B are prevented by presenting an alcoholic extract of yeast in which vitamin B1 alone is present, the deficiency of vitamin B2 was found by Chick and Roscoe to manifest itself.[9]

Though the etiology of pellagra is not yet completely cleared up, it is fairly certain that the central feature is a deficiency of a pellagra-preventing vitamin. The association of the disease with poverty or restricted maize diets is readily accounted for by the probable deficiency of "P-P" vitamin under these conditions. The occurrence of pellagra in certain individuals or groups of individuals and not in others on the same diet remains to be accounted for. Why, for instance, does pellagra occur among Durban prisoners and not among prisoners elsewhere in the Union on the same diet scale? It seems reasonable to suppose that a "P-P" deficient diet may produce a "subpellagric" state which is readily converted into overt pellagra by other factors. Such a factor would be hard work in intense sunlight, such as the Natal prisoners are subjected to in the Point and Congella Prisons.

A state of affairs similar to that of scurvy among Bantu labourers on the Transvaal mines would appear to exist. These labourers will arrive on the mine apparently healthy, although it is known that they have been subsisting in the native territories on a diet grossly deficient in antiscorbutic value. The mine medical officer cannot detect any physical fault in such a native, yet hard underground work will sometimes produce scurvy within a few weeks, although he has during those weeks been receiving the liberal mine ration with its carefully supervised amount of vitamin C contained in germinated beans, vegetables, etc.

The fact that there are pellagrins in Natal who have never been subjected to gaol conditions suggests that a large portion of the native population are in a subpellagric state. Such individuals, when admitted to gaol, will readily be converted into overt pellagrins by a monotonous, deficient diet combined with hard work in intense sunlight.

It would appear to be necessary to protect Natal native prisoners from pellagra by means of the addition to the ration of a "P-P"-rich substance such as yeast, in the same way as it has been found necessary to prevent scurvy on the Transvaal mines by the use of germinated beans. The native prison diets are grossly deficient, as will be seen from Table IV. It is probable that a relatively insignificant factor may tip the scale in favour of pellagra. Such a factor may be the grossly inferior bean ration which was issued to the Durban prisoners. In any case, the disappearance of the disease after the introduction of a good bean ration is significant. The "P-P" value of these good beans has apparently been sufficient to prevent the appearance of symptoms.

Summary.

Though the Bantus are largely and often almost exclusively maize-eating, pellagra has been rare in South Africa. There have been only three outbreaks of any significance—namely, in 1906 in Zululand, in 1912–13 in Pretoria Mental Institution, and a recent outbreak among Durban prisoners. These and a few isolated cases of which anything is known are tabulated.

The prison diet scales are uniform throughout the Union. The diets for natives consist largely of maize or mealies and are physiologically deficient. They are grossly deficient in "P-P" value. The fact that this diet resulted last year in pellagra in Durban and not in other parts of the Union must be attributed to contributory factors. Such a factor might be hard work in intense sunlight to which prisoners in the Congella and Point Prisons are submitted. In these two prisons the incidence of pellagra was higher than in the Durban Central Gaol, the inmates of which labour chiefly in the shade.

If the existing deficient prison diets are to be continued, it will be necessary under present conditions in Durban to supplement them by means of a substance rich in "P-P" vitamin, such as yeast. A similar procedure has been found effective in scurvy prevention among Transvaal mine labourers, who are protected from the scurvy brought out by hard underground work by the addition of highly antiscorbutic germinated beans.

THE BEAUFORT ARTIFICIAL LIMB WITH RECENT MODIFICATIONS.

BY

CHARLES W. CATHCART, C.M., F.R.C.S.,

CONSULTING SURGEON, ROYAL INFIRMARY, EDINBURGH.

This limb is simple in construction, moderate in price, and satisfactory in use. It was invented in Rome in 1851, by an Italian nobleman—Count Beaufort. His attention had been drawn to the need of an efficient artificial limb, at a moderate cost, to replace the old-fashioned "peg leg," which did not meet the requirements of the workmen. The Beaufort limb was made by a working carpenter without any special training in limb making. Additional help in the construction and distribution of the Beaufort limb was given by General Maxwell, a retired artillery officer, then living in Rome. His knowledge of physics enabled him to explain how to shape the Beaufort foot correctly, and his interest in the disabled workmen led him to form a small society to aid them with money.

MECHANICAL FEATURES.

Both the "thigh" and "below-knee" portions of this artificial limb consist of two side bars, an "inner" and an "outer." They are shaped to correspond to the outline of the leg which had been amputated. Each pair of bars is held together and strengthened by "distance pieces." (See Figs. 1 and 2.)

The upper ends of the "thigh bars" are united at the back by a well-padded half-hoop of iron. On this the patient bears his weight, when standing or walking, as a patient with a tuberculous knee-joint does on the ring of a Thomas's knee splint.

Joints are provided at the level of the knee on each side, to allow the limb to bend. The joint on the outer side is provided with a lock, by means of which the wearer can

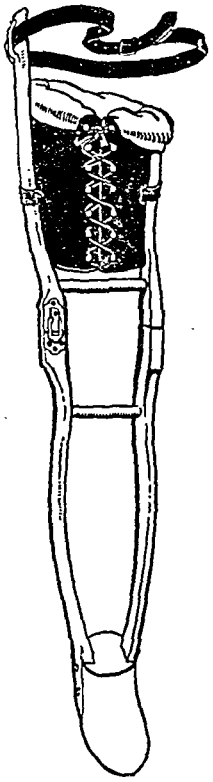

FIG. 1.

FIG. 3.

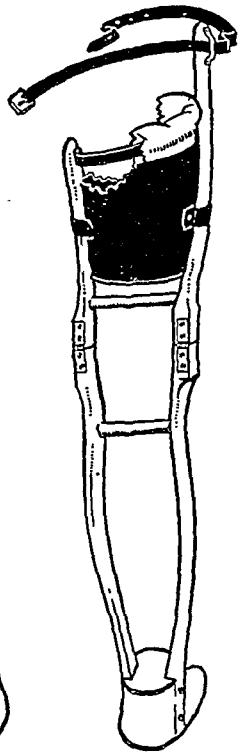

FIG. 2.

easily fix the limb in the straight position, when he wishes to stand or walk, and he can as easily release it.

Beaufort Foot.—The foot consists of a block of wood, curved on its under surface. On each side a slot is cut, into which the side bars are securely fitted. (See Fig. 3.)

From this brief description of the main features of the Beaufort limb it will be evident that no attempt is made to copy exactly the shape of the human leg. This disadvantage, from an aesthetic point of view, is not important, because artificial limbs are concealed, in any case, by the clothes of the wearer. It is well to bear in mind, however, that, although the expensive artificial limbs now in use have joints at the knee and ankle, they have no mechanism to take the place of muscles. The curved sole of the Beaufort limb affords the wearer a satisfactory resemblance to the normal movement of the body in walking.

MEASUREMENTS FOR THE ABOVE-KNEE LIMB.

The following measurements should be taken: The length of the stump from the fork to the end. The circumference (1) at 1 inch below the fork, (2) at the middle of the stump, (3) at 2 inches from the end, and (4) upon the pelvis between the great trochanter and the crest of the ilium (for the pelvic belt). The outline of the foot.

MATERIALS AND INSTRUMENTS REQUIRED.

1. *For the leg bars:* A block of tough wood, such as beech, 24 by 12 by 1¾ inches. Mark its long edges "A" and "B" and its short edges "C" and "D."

2. *For the foot* (large size): A block of well-seasoned wood, such as beech, 10 by 4 by 4 inches.

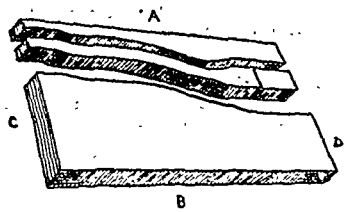

FIG. 4.

3. *Two strong brass "bagatelle" hinges*, 4 inches long, 5/8 inch broad, 1/8 inch thick, strong brass screw nails, and tools for insertion. (See Fig. 2.)

4. *A band saw, a bow saw, or a keyhole saw*, to cut out the bars from the large block, and to shape the small block for the foot.

5. *An "attaché case bolt."* This consists of two sections. (See Fig. 6.)

6. *For the thigh corset.* (1) A rectangular piece of strong, pliable leather, such as cowhide; *length* equal to the distance from the "fork" to a point 4 inches above the knee level; *breadth* 1 inch less than the circumference of the thigh at the fork. (Feel for the knee-joint at the upper edge of the head of the tibia.) (2) Several eyelets, special forceps to cut out the holes, and "closing" forceps to fix the eyelets in position. (3) Laces to close the corset. (4) A pelvic leather strap to surround the pelvis of the patient. (5) A small strip of bridle leather, 3 inches long and 1 inch broad, to be fixed vertically to the top of the outer bar by a screw nail at each end to keep the pelvic strap in position. (See Fig. 2.)

7. *A piece of hoop-iron*, 1 inch broad, 1/8 inch thick, and in length three-quarters of the circumference of the thigh just below the tuber ischii. This is required for the support of the tuber ischii. (Fig. 2.)

8. *Distance pieces.* These are short transverse bars of wood, about 3/8 inch thick, fitted into the side bars of the artificial limb, to afford the necessary rigidity. The length of these pieces is governed by the breadth of the stump. (See Figs. 1 and 2.)

9. *For drawing the contour lines.* Obtain three or four sheets of firm white paper, *in length* equal to the distance from the crest of the ilium to about 2 inches below the knee-joint, *in breadth* a few inches broader than the thigh.

INSTRUCTIONS FOR MAKING THE BEAUFORT LIMB.

Side Bars.

The shape of these bars is obtained (1) by tracing the *contours of the sound thigh and leg on paper:* (2) *by cutting* out the patterns thus traced; and (3) by reversing the patterns.

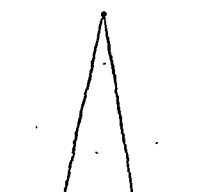

FIG. 5.

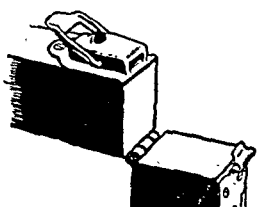

FIG. 6.

The reversed patterns afford the contours required for the artificial limb.

1. *Contour for the Upper Outer Bar.*—Lay a sheet of the required paper on a firm, smooth surface and place the patient's thigh upon it. Then, with a long pencil held vertically, trace the outline of the thigh on the outer side, from the crest of the ilium to a point 2 inches below the level of the knee-joint. Mark the position of the knee-joint.

2. *Contour for the Upper Inner Bar.*—Trace similarly the inner side of the leg from the "fork" to a point about 2 inches
[illegible] Mark the position of the knee-joint. Lift
draw a line between the marks which
Mark the surface of the paper with a
cross. Then cut the paper along the contour lines, and the line

which indicates the knee-joint. Reverse the paper, position its contours will correspond to those of the amputated leg.

3. *Contour for the Lower Outer Bar.*—Lay the leg upon another sheet so that its upper edge is 2 inches above the level of the knee-joint. Then, with a long pencil held vertically, trace the outer side of the leg from the upper edge of the paper downwards to a point 1 inch above the outer ankle. From that point continue the line straight to the sole of the foot.

4. *Contour for the Lower Inner Bar.*—Draw a similar contour *in every detail* on the inner side of the limb. Mark the paper to indicate the level of the knee-joint on each side. Lift the leg, and indicate this surface by a cross. Then cut along the contour lines, and the line which indicates the position of the knee-joint.

To obtain the contour of the bars required reverse the contour of the bars by laying the marked surface downwards.

To shape the upper outer bar: Place the above-knee portion of the reversed paper pattern upon the block of wood as follows: (1) Let the edge of the pattern at the knee level lie upon edge "C" of the block of wood. Then, while it still lies over that edge, move the pattern towards edge "A" of the block till its most prominent curve comes to about 1 inch distant from edge "A." Mark the contour of this pattern on the block. (2) Now, while the knee level of the pattern is still lying over edge "C," move the pattern towards edge "B" for 3/4 inch and mark the contour on the wood again.

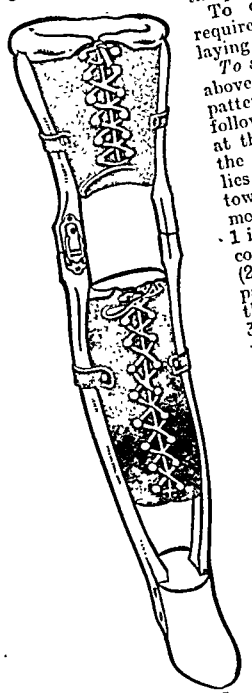

FIG. 7

N.B.—To provide a greater thickness of this bar for the knee lock put a mark 1/4 inch nearer edge "A" in advance of the first contour line, and carry a new line for 3 inches towards the trochanter end of the bar at the same distance—that is, 1/4 inch in advance of the first contour line. Then taper the line gradually nearer to the first contour line till the two lines join. (See Fig. 4.)

To shape the lower outer bar: Repeat this procedure, including the extra thickness for the knee lock, but carry the additional line towards the foot, instead of towards the trochanter.

To shape the upper inner bar (not to be thickened): Place the pattern of the inner side of the thigh on the block with the "knee level" laid over either side "C" or side "D," as is most convenient. Advance the pattern till its most prominent part is within 1/2 inch from the adjacent long edge. *Mark this contour* on the block of wood. Then, while still keeping the knee level of the pattern lying over the required short side of the block ("C" or "D"), withdraw the pattern for 3/4 inch from the first contour line and mark a second contour line on the wood. This interval will correspond to the required bar when cut out by the narrow-bladed saw.

To shape the lower inner bar: Trace upon the block of wood the contour line taken from the inner side of the leg, from the level of the knee-joint downwards to a point about 1 inch above the ankle. From that point continue the line straight to the sole of the foot. Repeat the same contour at a distance of 3/4 inch from the previous one. With a narrow bladed saw cut vertically through the block of wood, following the contour lines marked on the wood.

Beaufort Foot.

The correct formation of this part is essential. The curvature of the sole is of great importance. Mark one end of the foot-block as the heel, and the other as the toe. Determine which surface is to be the sole. On the sides of the block describe an arc of a circle, the distal edge of which reaches the lower margin of the block, while its radius is equal to the length of the sound leg from the knee-joint to the ground. Upon the circumference of that arc mark off a length equal to that of the sound foot. Thus section of the circle will indicate the curve required for the foot. Lastly, shave away the wood till the plane reaches the curved line. Nail a strong layer of durable leather upon the sole. (See Fig. 5.)

Attaching the Side Bars to the Foot.—On each side of the shaped block, at a position which corresponds to that of the inner ankle, cut a slot down to the sole $1\frac{1}{4}$ inches broad and $\frac{3}{4}$ inch deep to receive the straight lower ends of the bars. Secure them in position with glue and two screw nails on each side. Shape the fore part of the foot to resemble an instep. Round off the corners of the block. (See Fig. 3.)

Knee-joint.

(*a*) For the two *inner* bars, one above and one below the joint. With strong screw nails fix the plates of one of the hinges upon the posterior surfaces of these inner bars. Make sure that the interlocking edges of the brass plates lie over the line of the knee-joint. This will allow the lower bar to bend backwards towards the upper one, or vice versa. (*b*) For the two *outer* bars, one above and one below the knee-joint. (Note that this joint has the lock attached to it.) Fix a hinge to the posterior surfaces of these bars, as described under paragraph (*a*). (See Fig. 2.)

The "Attaché Case Bolt."—This appliance has two portions, which can be easily clamped together or released by the fingers of the wearer acting through the clothing. The straight edges of the foot-plates of the lock are placed on the front surface of the bars with their edges in contact with one another, over the line of the knee-joint. Fasten the foot-plates securely with screw nails to the upper and lower bars respectively. (See Fig. 6.) When no stump intervenes connect the bars above and below the level of the knee-joint with distance pieces. (See Figs. 1 and 2.)

Bearing of Weight.

(*a*) *Tuber-bearing Half-ring.*—Rivet this half-ring to both upper bars, at the level of the top of the inner one, thus leaving a sufficient projection on the outer bar for the attachment of the pelvic strap. Pad this half-hoop well with felt, on the top edge and inner surface. (See Fig. 2.)

(*b*) *Leathern Corset.*—Wrap the longer portion of the leather transversely round the thigh from the fork down to a point 4 inches above the knee level. This will cause overlapping of the leather on each side, especially near the knee. Draw lines on the leather where the two sides meet. Make it fit comfortably over the thigh. Cut away enough superfluous leather to leave in front a gap of 1 inch from top to bottom. This allows for stretching of the leather and shrinking of the thigh. Cut away superfluous leather at the top and bottom to make the upper and lower borders of the corset horizontal. Attach the corset to the side bars by two rivets on the inner side of each bar. Make the upper border of the corset lie inside the half-hoop ring. Fix the eyelets down the front for closing the corset, and insert a lace for tightening. Secure the leather pelvic strap to the top of the outer thigh bar by the leather loop, which must be screwed vertically to the bar. (See Figs 1 and 2.)

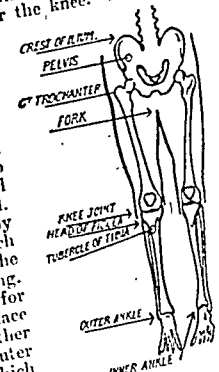

FIG. 8.

MEASUREMENTS FOR THE BELOW-KNEE LIMB.

Length of stump from the tubercle of the tibia to the end of the stump. Circumference (1) of the thigh 1 inch below the fork, (2) of the thigh 4 inches above the level of the knee-joint, (3) of the stump at the level of the tubercle of the tibia, (4) at the mid-point of the stump, and (5) at 2 inches above the end.

CONSTRUCTION OF THE ARTIFICIAL LIMB FOR THE BELOW-KNEE AMPUTATION.

Provide the following: (*a*) A tuber-bearing ring as described for an artificial limb for a thigh stump. (*b*) Side bars, the joints and locks as for a thigh stump. (*c*) A foot (see Fig. 3). (*d*) A leather corset to support the thigh as in the case of a thigh stump. (*e*) A leather corset to embrace a below-knee stump, similar in construction and attachment to that described for a thigh stump; *length*, from the tubercle of the tibia to half an inch below the end of the stump; *breadth*, (*a*) equal to the circumference of the head of the tibia at the level of the tubercle, and (*b*) equal to the circumference at the lower end of the stump. (N.B.: A leather pelvic strap is *not* an essential part of a below-knee leg.) (See Fig. 7.)

SYME'S AMPUTATION: MEASUREMENTS FOR SYME'S LIMB.

Take a contour of the affected limb from below the head of the fibula downwards, round the end of the stump, and up to the same level on the inner side. Note circumference (1) just below the head of the fibula, (2) at the mid-point of the stump, (3) at its narrowest part, and (4) at the bulb end. Note diameters at the end of the stump from side to side, and from back to front. Measure the length and breadth of the sole of the sound foot.

CONSTRUCTION OF THE BEAUFORT "SYME'S AMPUTATION" LIMB.

Make the foot as described for a thigh stump, except that the depth of the foot-block must not be more than 2 inches. Make the two side bars the same in thickness and breadth as pre-

viously instructed, except that the length of the bars must not reach higher than to a position half an inch below the head of the fibula. Fit the bars into slots in the foot, as indicated in Fig. 3.

Socket.—Procure a piece of strong leather—*length*, from above the bulb of the stump to below the head of the fibula; *breadth* equal to the circumference of the stump. Rivet this leather to the inner sides of the bars. Insert eyelets for lacing the socket. The end of the stump, which is not enclosed, rests on a soft pad on the top of the artificial foot. Line the socket down the front with felt, or similar substance.

CHOPART'S AMPUTATION.

This amputation only requires the patient's boot to be filled up with firm stuffing to replace the lost portion of the foot.

THE TREATMENT OF PNEUMONIA IN CHILDREN BY SUBCUTANEOUS OXYGEN.

BY

T. McCOWATT MONTFORD, M.B., CH.B.GLAS.,

LATE ASSISTANT MEDICAL OFFICER, BOOTH HALL INFIRMARY FOR CHILDREN, MANCHESTER.

THE active treatment of pneumonia has long been augmented by the administration of oxygen. Those of us who have given the gas by intranasal catheter or inverted funnel have advocated it for its psychological rather than for its therapeutic benefit.

The value of oxygen administered subcutaneously has been by no means definitely authenticated, and therefore, with the object of investigating the immediate effects on the patient, and the more lasting effect on the course of the illness, 179 children admitted to my wards in Booth Hall Infirmary, Manchester, between November, 1928, and April, 1929, were treated with relatively large doses of oxygen injected into the subcutaneous tissues. Each case of acute pneumonia, irrespective of the type, etiology, or severity of the disease, coming under my care received oxygen as early as possible. It should be observed that the ages of the children varied from a few weeks to 16 years, and that the hospital recruits its patients from poorer-class Manchester districts where in winter child debility is widespread.

As a control, I have made notes on 89 consecutive cases admitted to Dr. I. A. Milne's wards during the same period to which subcutaneous oxygen was not administered.

In each series simple expectorant and counter-irritant remedies were employed as seemed indicated in each particular case. All were nursed in open-air pavilions in charge of the same sisters. To my regret, several patients who had received treatment were removed by parents before recovery was complete.

Dosage.

Mr. T. S. Kirk[1] found that the area of skin raised from the chest wall by 100 c.cm. of oxygen slowly injected was equal to the area covered by the palm of a man's hand. This rule was found to be fairly accurate, and was followed in this series, 50 to 200 c.cm. being injected at a time. Generally two or more doses were given. If on the day following the first treatment the temperature had not fallen, or if it had fallen and then became raised, as was a frequent occurrence, a second dose was administered. The average aggregate dosage was: up to 5 years of age, 200 c.cm.; from 6 to 10 years, 300 c.cm.; from 10 to 16 years, 400 c.cm. It was interesting to remark that whereas the absorption commenced in a few minutes, an oxygen emphysema was almost invariably felt for twenty-four hours or longer.

Method.

Rubber tubing was connected up to a cylinder of oxygen, and, with aseptic precautions, the gas was allowed to escape slowly through a hypodermic needle under the skin. About five minutes were taken to run in 100 c.cm. Specially warmed oxygen appeared to be without additional advantage. The hypodermic puncture was sealed with collodion, as the oxygen readily escaped. This simple procedure was unconnected with pain or discomfort, older children describing the sensation as similar to that produced by water trickling over the skin. In no case was there associated shock or other general disturbance, or abscess formation.

Immediate Effects.

Within four hours after the injection the temperature, as a rule, fell—sometimes to normal. This was accompanied by a partial fall in the pulse rate. The lowering in the pulse and respiration rates was less obvious than the temperature fall. Dyspnœa was eased. If cyanosis was a feature, within an hour the colour was improved. In four cases of pulmonary tuberculosis with cyanosis treated by this method a similar phenomenon was noted. Unfortunately, in all four relief was transitory, and the course of the disease either was not affected or it was expedited. No improvement occurred in the congestion of the face of a girl suffering from acute rheumatic myocarditis. The patients soon became less distressed (roughly in four to twelve hours), and as a rule slept comfortably. On the following day the general condition was improved except in some of the fatal cases. In no case did a crisis take place, the temperature falling by lysis.

In the first 50 cases—where it was possible without interfering with sleep—the temperature and pulse and respiratory rates were taken half-hourly for forty-eight hours. Nothing other than the remarkable variability in these phenomena was noted.

An early necropsy was performed on the body of a patient who died a few hours after administration. There was no evidence of oxygenation of the pulmonary tissues; the blood was dark, the bright redness described by Mr. Kirk not being observed.

Death Rate.

The following table indicates the percentage death rates in the various types of pneumonia.

	Oxygen Series.		Control Series.	
	Number.	Death Rate	Number.	Death Rate
		Per cent.		Per cent.
Total number of cases ...	179	25	89	25
Broncho-pneumonia ...	130	33	54	33
Lobar pneumonia	49	2	35	2
Primary pneumonia ...	121	23	71	20
Secondary pneumonia ...	58	28	18	33
Influenzal pneumonia ...	22	9	7	14

It is thus apparent that it cannot be claimed that the use of subcutaneous oxygen has a beneficial influence on the mortality.

Late Effects.

Pyrexia.—The average length of the febrile stage was shorter in the oxygen group.

	Oxygen Series.	Control Series.
Average length of febrile stage in all cases	10 days	13 days
Average length of febrile stage in broncho-pneumonia	10 days	15 days
Average length of febrile stage in lobar pneumonia ...	11 days	11 days

Duration.—The average length of the course of the disease was lessened in the oxygen series. The criterion of this was taken as the interval of time elapsing after onset before the chest was definitely cleared of adventitious sounds.

	Oxygen Series.	Control Series.
Average time in which chest cleared in all cases ...	23 days	29 days
Average time in which chest cleared in broncho-pneumonia	21 days	31 days
Average time in which chest cleared in lobar pneumonia	21 days	26 days

Conclusion.

From the cases investigated it was to be concluded that, whilst the injection of subcutaneous oxygen in pneumonia is without effect on the death rate, there is an immediate improvement in symptoms, with a curtailment of fever. The actual course of the disease itself is shortened by six or seven days. The reduction in the febrile period, and in the course of the disease, is more definite in broncho-pneumonia.

The definite alleviation of the toxaemia is not peculiar to pneumonia and seems quite apart from any specific action on the lung tissue *per se*. The toxaemia in a case of severe diphtheria was greatly relieved after injection of oxygen.

As a whole the pathological processes are apparently expedited. Possibly the stages of hepatization are hastened by an early formation of hydrogen peroxide in the pulmonary tissues.[2]

To the medical superintendent, Dr. J. D'Ewart, my thanks are due for permission to make use of the cases investigated.

BACTERIOLOGY OF THE TONSILS IN RELATION TO RHEUMATISM IN CHILDREN.*

BY

DAVID NABARRO, AND R. A. MACDONALD,
M.D., F.R.C.P., M.B., CH.B.,

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON.

IT has often been suggested that the infective agent in rheumatism, in regard to which streptococci have more often been incriminated than any other organism, is to be found in the tonsil. Whether it exerts its toxic influence from there, or whether it enters the body by that portal, and is then disseminated to other parts, has not yet been decided. If, however, specific streptococci are to blame, and their *locus* of rest or passage is in the tonsil, one would expect to find some difference in the streptococcal flora of the tonsil in rheumatic and non-rheumatic cases. To determine this point a number of rheumatic and non-rheumatic tonsils were investigated. The rheumatic tonsils came from out-patients with articular rheumatism, chorea, and heart conditions, all of whom had some degree of enlargement or sepsis in their tonsils. The non-rheumatic patients were those in whom the tonsils were enlarged or septic, and from whom no history of any rheumatic manifestation could be elicited. In each case an endeavour was made to isolate *all* the varieties of streptococci present in each tonsil so that the types might be compared.

Analysis of Streptococci from the Tonsils of Rheumatic and Non-Rheumatic Children.

	Rheumatic.		Non-Rheumatic.
Total tonsils	50	.....	48
Total streptococci	190	.....	157
Streptococci per tonsil	3.80	.....	3.27
Haemolytic	14.1%	.....	14.03%
Non-haemolytic	85.9%	.....	85.97%
Green	46.3%	.....	45.86%
Non-green	51.0%	.....	53.51%
Doubtful	2.7%	.....	0.63%
Mitis	44.2%	.....	37.0%
Salivarius	26.3%	.....	28.0%
Faecalis	4.2%	.....	3.18%
Pyogenes	12.6%	.....	11.5%
Other streptococci	12.7%	.....	20.0%

From this table it will be seen that the streptococci from the rheumatic tonsils do not differ materially, as regards the characteristics investigated, from those of the non-rheumatic. There is at present no really satisfactory classification of non-haemolytic streptococci, and this makes it difficult to draw a hard-and-fast line between varieties. Classification by means of sugar fermentation is not much to be relied on, and therefore, though we put in comparative differences in this particular, we fully realize its limitations. As, however, the conditions were always identical for cultures from the rheumatic and non-rheumatic series, even these variable tests should be of some assistance.

The appearance of the culture plates showed no marked difference, and even on Crowe's medium,[1] which shows the minutest changes in colony appearance, we were unable to tell a rheumatic from a non-rheumatic plate. As regards the number of streptococci isolated per tonsil, this is rather low, owing to the fact that in one case in each series there were no streptococci found, in one or two almost a pure growth of one variety, and also that in a few cases the organisms died before any of their reactions could be carried out. This, however, was the same for both series.

Most observers—Poynton and Paine,[2] Small,[3] and Birkhaug,[4] to mention only a few—who have described "rheumatic streptococci," have placed them in the non-haemolytic and non-green-producing group. Without trying to isolate any of these recognized varieties, it might be expected that rheumatic tonsils would show a higher percentage of inert streptococci. There was little difference in our series, the rheumatic being slightly lower. This is in agreement with the work of Hitchcock,[5] who found no greater incidence of inert streptococci in rheumatic fever throats.

Discussion.

For many years tonsillectomy in rheumatism has been advocated. Poynton and Paine (1900)[2] demonstrated their diplococcus in rheumatic tonsils, and in 1913 Poynton[7] says that unhealthy tonsils are very frequent in rheumatism. Again in 1925[8] he says that he believes successful removal of unhealthy tonsils to be a valuable prophylactic step in rheumatism when viewed on broad lines. Schicheld (1910)[9] claimed that removal of the tonsils cures the attack and prevents recurrence, and Hutchison (1911)[10] upholds his view, if not quite so emphatically. Pybus (1915),[11] Morris (1916),[12] and Langmead (1920)[13] all consider that tonsillectomy is advantageous, and in more recent years the British Medical Association report (1926),[14] Robey and Freedman (1927),[15] Kaiser (1927 and 1929),[16] and Wilkinson and Ogilvie (1928)[17] all recommend tonsillectomy.

From the observations of the above-named authors it would seem that rheumatic infection has a close connexion with the tonsil, and certainly any workers who have described definite streptococci as possible causes of rheumatism have been able to isolate the organisms from the tonsil. A number of different varieties are described, none of which seems definitely established, or is regularly isolated from every case. Birkhaug[4] made a considerable advance when he succeeded in preparing a soluble exotoxin from his non-methaemoglobin-forming streptococcus, and he published some interesting results of skin tests which gave a much higher incidence of positives in rheumatic than in non-rheumatic children. This finding has not, however, been definitely corroborated in this country. Indeed, Mackie and McLachlan (1927)[18] state that "the ability to produce toxic filtrates seems to rest in some peculiarity of this type of micro-organism" (streptococci), "rather than in a specific etiological role in respect of rheumatic fever."

To review briefly some of the results of earlier experiments, Cole, in 1904,[19] produced arthritis and endocarditis in rabbits by inoculation of streptococci from various sources, not necessarily rheumatic; and in 1913 Harrison[20] states that inoculation of "non-rheumatic" streptococci will produce arthritis, at times indistinguishable from that produced by *Streptococcus rheumaticus* (Poynton and Paine). Faber in 1915[21] produced a sensitization by giving more than one injection, and obtained arthritis in animals with a comparatively non-pathogenic green-producing streptococcus. Rosenow (1914)[22] isolated three different types of streptococci from joint fluids in fourteen rheumatic cases. Swift and Kinsella[23] showed in 1917 that there were considerable immunological and cultural differences in streptococci isolated from their series of rheumatic fever cases. Clawson (1925)[24] isolated green-producing streptococci from twenty cases of well-defined acute rheumatic fever, and Andrewes, Derick, and Swift (1926)[25] found haemolytic, non-haemolytic, and *viridans* streptococci in acute throats in association with rheumatic fever. The researches of these workers show a considerable diversity of possible causal agents in rheumatism, and they have isolated in most cases streptococci which are to be found

* The investigations upon which this paper is based were carried out by one of us (R. A. M.) during tenure of the Ida Schag-Montefiore Research Fellowship at the Hospital for Sick Children.

normally as saprophytes (so-called) in various parts of the body. It is difficult, on the supposition of a specific bacterial cause of rheumatism, to correlate this conflicting work, and indeed it seems reasonable to suppose that the soil is more important than the seed, and that any streptococcus present in a given patient may, in suitable circumstances, become the infecting agent. What these circumstances are has not yet been determined, but the sensitization by small doses of streptococcal toxin over long periods is a point of importance. Swift, Wilson, and Todd[26] suggest that patients may be made more sensitive to toxins by repeated skin test doses, and also that hypersensitivity seems to increase with age. They also think that type specificity does not exist. Swift, Derick, and Hitchcock[27] have gone a step further in this direction. They produced a hypersensitive state in rabbits, when a comparatively small dose of streptococci would produce a disproportionately severe result. Their conclusions represent an interesting hypothesis for the etiology of rheumatic fever.

"The theory is advanced that the pathogenesis of rheumatic fever can be explained by the existence in certain individuals of a condition of hypersensitiveness (allergy or hyperergy) to streptococci, resulting from repeated low-grade infections or from the persistence of foci of infection in the body. When under suitable circumstances streptococci or their products are disseminated to the tissues, these tissues over-react and the characteristic picture of the disease results. When, on the other hand, a state of immunity exists" (which they say may be developed by different dosage among other things) "the dissemination of streptococci results in a minimum of injury to the tissues, and the characteristic phenomena of the disease fail to appear."

To return to the tonsils, they may well be one of the foci in which these "repeated low-grade infections" occur, which would account for the undoubted advantages to be obtained from tonsillectomy in rheumatism. If, as has been suggested, the type of streptococcus is unimportant, then the fact of there being little difference between the rheumatic and non-rheumatic tonsils as regards their streptococcal flora is not of much importance, and cannot be used as an argument against tonsillectomy, as prima facie it might seem to be.

Conclusions.

1. Streptococci isolated from rheumatic tonsils do not differ materially from those isolated from non-rheumatic tonsils.

2. This absence of difference fits in with the theory that there is no specific streptococcus which is the cause of rheumatism, but that the condition is due to a hypersensitiveness resulting from repeated small doses of toxin.

3. The tonsil is probably one of the foci from which these toxins may be absorbed.

4. For this reason, in spite of the lack of difference mentioned above, tonsillectomy in rheumatic cases is probably a valuable prophylactic and therapeutic measure.

AN UNUSUAL INFECTIVE CONDITION OF THE BLADDER.

BY

E. WORDLEY, M.D.CAMB., M.R.C.P.LOND.,

PATHOLOGIST TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.

THE case of cystitis here recorded, in which an atypical bacillus was apparently the infecting organism, is of considerable bacteriological interest. The clinical details were as follows.

The patient, a man aged 65, had an acute attack of cystitis about ten years ago; since then he had been troubled with a mild degree of frequency of micturition at various times; he continued to pass a very turbid urine, and a diagnosis of prostatic abscess had been made. He reported that his urine had been examined bacteriologically on several occasions during the past ten years, and it had always contained much pus and, as he stated, *B. coli*. He was referred to me for the possibility of vaccine treatment.

Examination of the urine showed numerous pus cells and non-motile bacilli, which in stained films proved to be Gram-negative. Cultures on all the usual media were sterile. These results were repeatedly obtained, whether attempts were made to grow the organism aerobically or anaerobically. Finally, after numerous attempts, a small growth was obtained on agar to which human oxalated blood had been added. After several subcultures on this medium it became possible to grow it fairly readily on ordinary agar, and its cultural characteristics were further investigated, with the following results: gelatin was not liquefied; indol was produced in broth in overnight cultures; litmus milk was turned acid but was not clotted. When the organism was grown in sugar media—dextrose, maltose, dulcite, mannite, lactose, and cane sugar—they became acid, but no gas was produced.

At the time the organism was thought to be *B. coli anacrogenes*. Later on my attention was called to a paper by Bamforth,[1] in which an organism with very similar cultural characteristics, which was associated with a small outbreak of dysentery, is described, and related to the bacilli described by Sonne. Later still Nabarro's observations[2] on the relation between *B. coli anacrogenes* and Sonne's bacillus were noted; accordingly, further observations were made on my cultures. On plating the agar culture it was found that the colonies could be divided into rough and smooth forms. On litmus lactose agar plates both red and blue colonies were noted. On further forty-eight to fifty-two hours' incubation the colourless colonies showed central red papillae. The red colonies were thus coloured in twenty-four hours, and, as Nabarro points out, are not to be distinguished on plates from *B. coli*.

Both Dr. Bamforth and Dr. Nabarro very kindly sent me some of their antiserum, which they had prepared from their bacilli. Considerable difficulty was experienced in making stable emulsions, since, as White[3] points out, spontaneous agglutination is very apt to occur in rough forms of this group, and therefore emulsions in distilled water were used. In each case agglutination took place up to the end point of the two serums employed. Both were pooled serums, and were used on agar subcultures of mixed types of colonies.

The interesting features of this case are the unusual infecting organism and the curious fact that many times no growth could be obtained, although the urine was swarming with bacilli. No lysis of the cultures subsequently obtained was ever noted.

I might mention that recently I saw a similar case. The patient had cystitis, and microscopical examination showed very numerous pus cells and masses of Gram-negative bacilli, but no growth could be obtained; I was informed that a previous examination had given a similar result. Unfortunately I had no opportunity of examining this second case again.

At the present time the first patient's symptoms remain the same in spite of all treatment. The urine still contains numerous pus cells and masses of Gram-negative non-motile bacilli. The curious fact that has arisen now is that the bacilli described previously can be isolated without difficulty, so that one is uncertain whether the organism now isolated with ease is the same bacillus noted in every examination, but which could not be obtained by culture in many of the previous examinations. Morphologically it appears to be exactly similar. The patient's serum does not agglutinate this organism obtained from his urine.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

RUPTURE OF THE JEJUNUM.

The following case of an unusual sequel to a fall appears worth placing on record.

A healthy-looking lad, aged 18, walked into the accident room of the Eccles and Patricroft Hospital complaining of a head injury, the result of a fall over some rails. He was accompanied by a friend, who volunteered the information that the patient had also complained of his stomach. Examination of the abdomen showed no external evidence of injury, but there was some rigidity, though it was very difficult to be certain that this was real rigidity and not a mere nervous tightening of the abdominal wall. Pain was slight and epigastric in site, radiating towards the right shoulder. The temperature was 97° F., and the pulse 80. There was no nausea or vomiting. He had a desire to pass water, but was unable to do so. It was decided to admit him to the wards for observation. After admission his pain diminished, but did not entirely disappear. About an hour later he vomited twice, but the character of the vomit could not be clearly determined as he micturated in the same bowl. After vomiting he felt rather better, but the abdominal rigidity persisted

Mr. E. D'Arcy McCrea performed laparotomy, and the peritoneal cavity was found to contain a large quantity of brownish fluid, which was removed by swabbing. Examination of the bowel revealed a large tear in the jejunum, about six inches below the duodeno-jejunal flexure, the bowel showing almost complete separation. The bowel above the lesion was contracted, while the small gut below it was dilated. The bowel was sutured and the abdomen closed with two drains, one at the site of the lesion and one in the pelvis. The pelvic drain was removed after twenty-four hours and the other in forty-eight. The temperature fluctuated between normal and 100.4° F. for a few days after the operation, and remained normal after the third day. Vomiting on the second day after operation was easily controlled by small doses of tinct. iodi mit. Convalescence was otherwise uneventful, and the patient made a complete recovery.

The case presents several interesting features: rigidity was the only sign present; shock was entirely absent; pain was slight; vomiting only occurred once; and septic peritonitis did not supervene. The most striking point is the site of the lesion. A freely movable piece of bowel was ruptured by violence applied through the abdominal wall, whereas the usual site is the duodeno-jejunal flexure, where the gut is fixed to the posterior abdominal wall by peritoneum, and is unable to glide out of harm's way.

I am indebted to Mr. E. D'Arcy McCrea, F.R.C.S., honorary surgeon, for permission to publish this case.

J. B. Marinan, M.B., B.Ch.,
House-Surgeon, Eccles and Patricroft Hospital, Manchester.

ENDOCARDITIS WITH EMBOLI IN BOTH FEMORAL ARTERIES.

The case here recorded seems of sufficient interest to warrant publication.

On June 19th a man, aged 41, was admitted to the Brighton Infirmary with a vague history of illness starting one week previously with headaches, shivering, sweating, and pains in the chest. Two days before admission he temporarily lost the power in his left hand, which soon recovered. His past history included several attacks of malaria whilst in India (twenty-one years' army service there), cellulitis of the left leg from a bush scratch, and a bullet wound of the left thigh just above the knee in 1908.

On admission the temperature was 99.4°, pulse 104, respirations 26. He was obviously very ill; his face was grey and drawn; he was dull and lethargic, and he could not give a clear account of the onset of his symptoms.

On examination the heart was found to be slightly increased in size downwards and outwards. There was a well-marked systolic murmur to be heard at the apex, and limited to the apex. Blood pressure: systolic 94 mm. and diastolic 72 mm. The lungs and abdomen were negative. Central nervous system: the pupils were equal and reacted to light and accommodation; no knee-jerks were obtained. The plantar reflex was flexor on the right, no response on the left. There was no ankle-clonus. The left foot was bluish in colour and cold; there was complete loss of sensation below the left knee, and the veins were thickened on the inner side of the leg. There was no pulsation in the dorsalis pedis artery. Both femoral arteries pulsated equally well at the level of Poupart's ligament. At this stage the right leg appeared normal.

On June 21st the whole left leg rapidly became discoloured and cold. Two days later the right foot was cold and showed faint signs of bluish discoloration on the dorsum. The general condition of the patient at this stage was much worse, and he died the same evening.

A post-mortem examination was performed and the following were found. The heart showed external evidence of pericarditis, with roughening of the pericardium and a little more free fluid than normal. On opening the heart large vegetations were found on the mitral valve, parts of which appeared to have been recently broken off. The lungs were apparently normal. The spleen was enlarged, soft, and contained three large infarcts. There was infarction in the left kidney. The brain was congested. The femoral arteries were opened and a large embolus was found in each vessel at the junction of the femoral and profunda femoris vessels. There was no abnormality in the vessel walls.

The interest in the case was: (1) the exactly similar positions in which the emboli were found; (2) the fact that amputation of the left leg was considered (before the right foot showed signs of discoloration), but owing to the patient's general condition it was thought inadvisable to operate.

We are indebted to Mr. H. J. McCurrich for his help and for permission to publish this case.

Reports of Societies.

CAUSES OF EARLY ABORTION AND STERILITY.

The Sections of Obstetrics and Gynaecology and of Comparative Medicine of the Royal Society of Medicine combined on October 18th for a discussion on the causes of early abortion and sterility. The chair was taken by Mr. Arthur E. Giles, president of the first-named Section, who, in opening, urged the speakers to pay attention to terminology, for there was much confusion in this respect; the term "sterility" ought to mean incapacity to conceive, and consequently abortion should not be considered as a form of sterility.

Professor Arthur Robinson (Edinburgh), who introduced the subject, widened the president's definition; he preferred to define sterility as the incapability of a pair to produce living young who should survive until the natural period for their own reproduction and be themselves fertile. For the purposes of the discussion, however, he took sterility to signify incapability to produce living young. Sterility might be intentional or unintentional. Intentional sterility was more a sociological than a medical subject, and was outside the range of the present discussion. Unintentional sterility might be associated with inefficiency of the male or of the female, or of both male and female, or of neither male nor female alone, but of these particular two together; neither individual might be infertile with another partner, though their mutual union was sterile. The immediate causes of sterility could be grouped under various heads: injuries, malformations, or disease of the genital organs; non-production of mature germ cells on the part of one or other of the pair; or production of inefficient germ cells. Professor Robinson described a number of observations on horses, in which, out of some thousands of ova shed, 48 per cent. in the case of Clydesdale mares, and 58 per cent. in the case of thoroughbreds, did not produce young, although the matings had been carried out under control, and the stallions used were all in perfect health. How was this large proportion of unfertilized ova to be accounted for? Seeking for animals more convenient for experiment, Professor Robinson selected the ferret, and he gave particulars of an extended series of observations in which 165 ferrets produced 1,640 ova, about 39 per cent. of which did not produce living young—no results followed their union with spermatozoa. Both sires and dams were healthy, and were kept under ideal conditions; all were fed in the same way. Why did it so rarely happen that all the ova shed became converted into living individuals? The only explanation he could offer was that there was some disturbance of the chromatic arrangement in the nuclei. In some cases the spermatozoon of one male might not be able to unite with the ovum of a given female. It was well known that in the human species a pair might have no children, but, after divorce,

either, or perhaps both, might have children by other partners. There was a possible incompatibility between the germ cells of two members of opposite sex, with the result either that no fertilization occurred, or, if it did occur, the arrangement of the chromatic particles was such that the foetus was destined to perish prematurely, either before or after birth. Many abortions were due to the fact that the zygote produced by fertilization had continued to develop to a certain extent and had then died, really in consequence of the original incompatibility; by means of abortion nature took the easiest way of "cutting the loss" and beginning afresh the reproductive cycle.

Professor BECKWITH WHITEHOUSE (Birmingham) began by remarking that abortion in the human species was a phenomenon of common occurrence. The frequency varied in different countries, but the criminal practice of the termination of pregnancy vitiated the value of the figures in so far as they might have furnished any guide to the frequency of natural abortion. He furnished figures based on an investigation of 3,000 patients admitted to the gynaecological clinic at Birmingham General Hospital. In 11,430 pregnancies there were 1,972 abortions. The number of patients who aborted was 1,064, or 35 per cent. of the total. The statistics related to two periods—namely, 1909–13 and 1924–28. The percentage of abortions to pregnancies in the pre-war period (17.7) was slightly higher than in the post-war period (16.9). For a gestation to progress in a normal manner, Professor Whitehouse continued, the following conditions must be present: the germ-plasm of the oöcyte and spermatozoon must possess adequate initial vitality; the zygote must be implanted in a favourable position for its subsequent development; and the nutrition of the ovum must be maintained by an adequate supply of food factors in a suitable uterine environment. The natural and normal site of attachment of the zygote was the decidua of the upper uterine segment. Many abortions after the twelfth week of gestation appeared to be associated with a low placentation in the region of the os internum. The proper development and function of the decidua were all-important for the growth of the zygote. Since the growth of the decidua was dependent upon a hormone elaborated in the corpus luteum, lesions in the ovaries might account for many of the early abortions associated with uterine fibroids, displacements, and the like. Inasmuch as the Graafian follicle and corpus luteum were liberally supplied with nerve elements, inhibition of the latter might be the cause of the "reflex abortion" which followed mental or physical shock. A diseased decidua furnished a pathological environment to the developing ovum, and therefore anatomical lesions such as inflammation or hypertrophy of the endometrium might be responsible for disordered function. About half the ova that were aborted during the first three months of gestation were apparently pathological. Lesions not only affected the embryo, but were equally common in the foetal membranes. Many aborted ova consisted of the amnion and chorion only; the embryo had been absorbed. Embryologists considered that pathological ova were the result of an abnormal environment and were not caused by any inherent factor in the germ cells. The influence of environment was shown by the embryos present in tubal gestations, 86 per cent. of which appeared to be pathological. Experiment had also shown that by the use of various chemical solutions it was possible in the case of the eggs of certain fishes, sea-urchins, and frogs to produce from normal cells every form of anomaly known to occur in man, including such important lesions as spina bifida and anencephalus. It appeared, therefore, that impairment of nutrition (the result of faulty implantation, of abnormal food factors, or of various toxins) might be a potent factor in the cause of many obscure early abortions. The maintenance of nutrition was effected differently in various mammals. In some ungulates the secretion of the uterine glands, known as "uterine milk," was the sole source of nutriment to the developing embryo. In the human species, although the secretion of the uterus contained important reserves of calcium and iodine, the zygote depended upon materials in the maternal blood, except for a very short period in its life. Certain food factors appeared to exercise a very important influence upon the life and well-being of the ovum and foetus: thus, the value of iodine was being appreciated more and more in the raising of animal stock and in egg production. On a Staffordshire farm sows receiving iodine fallowed 50 per cent. more young than those having no iodine. An adequate supply of calcium was equally important. Finally, the work of Evans and Burr upon the existence in certain vegetable leaves and seeds of a specific anti-sterility food factor known as vitamin E would, if confirmed, open up a new and important field both for the investigation of the cause, and also for the treatment, of repeated abortion. The vitamin resembled in certain of its reactions the ovarian follicular hormone, although a wide divergence existed in the matter of solubility. Professor Whitehouse related one case in which a married woman, after having had two stillbirths and one abortion, was at her next pregnancy put upon a diet of vitamin E and calcium lactate and a preparation of ovarian hormone. A healthy child was delivered by Caesarean section. In a second case, after the woman had produced her first child prematurely, and her second child had spina bifida, she was placed on a similar diet and a healthy child was delivered.

Veterinary Experience.

Mr. J. R. BARKER discussed abortion in cattle, the causes of which, he said, were lack of power of the morula to absorb nutrient materials, the absence of such materials, the presence of deleterious materials, the absence of placental areas, and a definitely diseased endometrium. Sterility in cattle was only a state preceding an early abortion, and was due, in the main, to the same underlying agencies. The causes of sterility might be summarized as failure of the male to produce perfectly functioning spermatozoa owing to orchitis; failure of a functioning spermatozoon to reach the ovum, owing to vaginitis, cervicitis, endometritis, or salpingitis; failure of the ovary to produce a perfectly functioning ovum, due to ovaritis; and failure of the ovum to reach a favourable position for fertilization in the Fallopian tube, as a consequence of salpingitis.

Mr. O. STINSON said that in cattle abortion was due to the bacillus of Bang: this was taken in by the mouth. He had noticed that many cows affected would go on to full term, but be sterile afterwards, never conceiving again. He had also noticed an increased incidence of abortion and retained placenta in years when, owing to climatic conditions, the hay was musty. Mr. STEWART R. DOUGLAS, president of the Section of Comparative Medicine, agreed that the most serious abortions in veterinary practice were undoubtedly due to bacillary infection, though in human abortions, he thought, the infection factor was never mentioned. Nevertheless, if gynaecologists and bacteriologists would co-operate in examining samples of the uterine contents immediately on abortion, it was possible they might find evidences of bacterial causation. The greater part of the remaining discussion was occupied with the question of abortion in cattle, one speaker stating that it had been shown that of cows affected with contagious abortion approximately 30 per cent. passed the abortion bacillus—the bacillus of Bang—in the milk supply.

Mr. ARTHUR GILES said that in gynaecology the knowledge of sterility and abortion seemed to have come to a standstill; therefore the experience of veterinary colleagues might prove stimulating. He was a little confused by the apparent contradiction as between Professor Robinson and Professor Whitehouse. The former appeared to take the view that pathological ova were due in a measure to conditions inherent in the germ cells, and not exclusively to environmental defects, whereas Professor Whitehouse had claimed that pathological ova were the result of abnormal environment, and were not caused by any inherent factor. Professor ROBINSON repeated his belief that in many cases the cause was inherent, though he would not exclude environmental abnormalities as the cause in other cases. Professor WHITEHOUSE mentioned that on one occasion he had been able to isolate the bacillus of Bang from a uterus after abortion; this was in the case of a woman living on a farm. After that case he took cultures from the next fifty abortions, but did not find it again.

Reviews.

PROBLEMS IN SURGERY.

The mature reflections of a surgeon with such a vast experience as Crile could scarcely fail to be full of interest. In *Problems in Surgery*[1] the author, in the form of a series of lectures, has given to the world some of the results of his wide experience, and we venture to say that there is no one engaged in the practice of surgery who will not learn something from almost every page. Written in an intimate and conversational style, and dealing quite obviously with the everyday work of the author, the lectures are full of practical hints and of reflections which are always suggestive. The lectures deal, in order, with the management of acute infections, pre-malignant and malignant disease, operations on the bad-risk patient, hyperthyroidism, and certain difficulties in diagnosis and problems related to shock. In every lecture the originality and directness of the author are in full evidence, and although his statements are dogmatic they are always supported by substantial reasons. Of all the chapters those on the bad-risk patient and on the management of acute abdominal infections will appeal most to the general surgeon, and we would most strongly recommend the book to his attention.

THE MECHANISM OF THE LARYNX.

In spite of the fact that the study of the larynx and its diseases has been pursued unremittingly for the last half-century and is responsible for a large and expanding literature, comparatively little work has been done to increase our knowledge of the mechanism of the organ. The subject has not awakened the interest it deserves, and textbooks may be searched in vain for enlightenment. This may in some measure be explained by the tendency of laryngologists to fix their gaze upon the larynx as a medium of voice, and to ignore other physiological aspects of importance and significance. The gaps in our knowledge Mr. V. E. Negus has set himself to fill, and in *The Mechanism of the Larynx*,[2] after tracing the reason for the existence of the larynx and the steps of its evolution, provides us with an admirable study of the normal mechanism made from the biological standpoint and extending throughout the animal kingdom. From the wealth of material in the gardens and laboratories of the Zoological Society which has been at his disposal, he has been able to study the larynx in a wide range of animal species. Some of his results have already been embodied in illuminating papers and lectures, and he has supplemented his work by a careful study of the physiological aspect of the subject and widened his horizon by a knowledge of phonetics. The result is a book conceived in the scientific spirit, with the facts analysed with great care, and distinguished by a judicious and impartial outlook which shows the author more concerned to understand the problems than to hurry to a solution of them.

An excellent chapter on the evolution of the larynx reminds us that the organ is primarily developed as a valvular mechanism to protect the entrance to the pulmonary air-way, and that it is incorrect and misleading to speak of it as the organ of speech, though in course of evolution it has acquired other functions as well. Concerning its modification for olfaction, Mr. Negus points out that nasal respiration is primarily adapted for olfactory reasons, that coaptation of larynx and nasopharynx has for its primitive object the maintenance of the sense of smell while the mouth is open—mechanism made perfect by means of the epiglottis, which is primarily evolved for olfaction. All keen-scented animals have a big epiglottis in contact with a long soft palate. The needs of respiration explain other modifications, various factors interacting to give man a tract incapable of carrying a large supply of oxygen to his lungs, though this is not the cause of his inferiority in speed, but is a degenerate characteristic associated with lack of O_2 and CO_2 carriage in the blood. It is noted how the air tract has undergone many modifications to make the passage of air along it as frictionless as possible. The protective closure of the glottis is a primitive function, though in man closure takes place at the level of the aryepiglottic folds and not at the glottis. In its modification for deglutition it may be seen in various types how the larynx has responded to the necessities of the individual in regard to deglutition associated with olfaction and respiration, and how the type of food in its influence on the formation of a lateral food channel exerts a preponderating effect. For the regulation of intrathoracic pressure attention is directed to the larynx in its role of an air valve, and the view is expressed that in the larynx an organ has been evolved particularly by arboreal animals to subserve locomotion, prehension, olfaction, and deglutition, and that by the various modifications brought in an instrument has been provided capable of use for sound production in a highly efficient form.

The mechanism of phonation receives full discussion in an important chapter, and the author states his conclusion that throughout the animal world it is not by the anatomical structure of the larynx with which it is provided that the powers of phonation of the majority of species are decided, but by the use to which such an organ is put. Man follows this general rule. He possesses a larynx degenerate in most respects, but accidentally well adapted to phonation. The physiological anatomy of the larynx is dealt with in a concluding chapter, and an appendix contains a suggestive paper on observations on the evolution of man from the evidence of the larynx. The book is well provided with excellent illustrations—all except four being original—and with a copious bibliography which might have been stronger in foreign sources.

We are confident that this book will receive the cordial recognition it deserves. It is characterized by great industry and equal accuracy, and the clear insight it displays will make it invaluable as a volume of reference to all who desire to understand the basis on which laryngology rests. Its logical arrangement and its wealth of illustration, drawn from the whole animal world, make it most interesting reading, and its great practical value to the laryngologist is foreshadowed by the many points of contact which shed light upon problems that he himself is endeavouring to solve. Mr. Negus's book may be regarded as a worthy complementary volume to another work from the same school—Sir StClair Thomson's well-known textbook—and King's College Hospital may well be gratified by the issue from its throat department of two notable contributions to British laryngology.

THE BIOLOGICAL ACTION OF LIGHT.

The First International Conference on Light took place last autumn at Lausanne and Leysin, and the proceedings have now been published in book form.[3] So many and various are the aspects of the subject dealt with that the volume forms a précis of modern knowledge and opinion concerning light and its therapeutic applications.

Dr. Dorno of Davos, where accurate measurements of sunlight have been made continuously for many years, suggests in his paper that the significance of skyshine as a source of ultra-violet radiation has been neglected, and that the other tracts of the solar spectrum should not be excluded from therapeutic consideration. Professor Leonard Hill also stresses the importance of skyshine as a source of ultra-violet radiation, and points out that sunlight treatment can be carried out on a cloudy day or in the shade, a matter of practical importance in the treatment of febrile cases that should not be exposed to the heat of the direct sun; he maintains that a curative effect can result from such exposure of the body independently of the production of erythema. In his communication he includes a description of his acetone-methylene blue method of measuring the biologically active ra[illegible] obtained thereby

[1] *Problems in Surgery.* By George W. Crile, M.D. Edited by Amy F. Rowland. Philadelphia and London: W. B. Saunders Company. 1928. (6 × 9¼, pp. 171; 42 figures. 18s. net.)

[2] *The Mechanism of the Larynx.* By V. E. Negus, M.S.Lond., F.R.C.S.Eng. With an introduction by Sir Arthur Keith, F.R.S. London: W. Heinemann (Medical Books) Ltd. 1929. (Sup. roy. 8vo, pp. xxx + 523; 160 figures. 45s. net.)

[3] [illegible] *Lumière.* Paris: L'Expansion [illegible] 548; illustrated. 60 fr.)

in many parts of the world. The contribution of Fabry and Buisson also concerns the solar ultra-violet radiation. They note that though the light output of the sun is substantially constant, it is subject to considerable variations as we receive it, and while the earth's atmosphere absorbs and thus reduces the sun's radiations, it does so in degrees differing with the wave-length concerned, the shorter waves being especially absorbable. The nature of pigment formation in response to light is discussed by Bloch of Zürich, and other communications refer to the phenomena of hypersensitiveness. A. F. Hess of New York, in his paper on irradiated foods and sterols, summarizes the salient facts about the history of this subject, and discusses its theoretical importance and its bearing on the treatment of rickets and other states of calcium deficiency.

Dr. Roussel of Lamotte-Beuvron describes heliotherapy as an important adjunct in the open-air treatment of pulmonary tuberculosis, especially in the less severe cases. He believes that the indications for dosage should be based less on the anatomical extent of the disease than on its activity, acute tuberculosis being a contraindication. His paper is followed by an extensive and useful bibliography. Dr. Ceresole of Venice stresses the importance in therapy of climatic changes, noting that even small geographical variations may be associated with considerable differences in the therapeutic value of the solar radiations. At the Lido the amount of ultra-violet radiation is much enhanced by reflection from the water surface, and there is great reflection of heat from the sand; it is thus possible, by slightly varying the location, to graduate at will the amount and kind of radiation to which it is desired to expose the body. Dr. Reyn of Copenhagen deals with the administration of general light baths in the treatment of skin tuberculosis, as an adjunct to local actinotherapy, and gives details of the improved results which have followed this extension of the treatment.

Dr. Bernhard of St. Moritz, one of the pioneers of heliotherapy in surgery, presents a highly interesting account of the history of the subject since 1886. His experience with surgical tuberculosis concerns over two thousand cases. In 1904, when he was almost alone in this field, he was followed by Dr. Rollier, who developed treatment by sunlight on a large scale. Dr. Rollier himself has dealt with many thousands of patients, and the routine, yet pliable, system of sun bathing which he has elaborated is now practised in all parts of the world. For some years he has held at Leysin an instructional course on heliotherapy, and the homage paid to him by Dr. Rosselet of Lausanne was echoed by many pupils. Dr. Rollier was in a very real sense the nucleus of the conference. Additional interest was given to the proceedings by demonstrations at Leysin and some excursions in the vicinity. The mention of these will recall to many their enjoyment of a pilgrimage to Rollier's clinics.

A FREUDIAN VIEW OF THE NEUROSES.

Professor Israel Wechsler's *The Neuroses* is the expansion of a chapter devoted to the consideration of that subject in his *Text-book of Clinical Neurology*, which was reviewed in our issue of January 21st, 1928 (p. 100). We learn from the preface to the present work that that chapter received favourable comment from many of the author's colleagues, and was honoured by the personal appreciation of Professor Freud. The chapter in question, appearing as it did towards the end of a work on organic neurology, came as a surprise to readers who had hitherto been immersed in neuro-anatomy and neuro-physiology, for Professor Wechsler in his study of the neuroses threw all such conceptions aside in favour of a purely psychological method of approach. In adopting this attitude Professor Wechsler frankly contended that it was more important for an understanding of the neuroses to know why a person did a certain thing than how he did it, and the latter belonged, in his opinion, to the field of neuro-anatomy and neuro-physiology. While not denying that for every mental process there was an underlying and accompanying [illegible] admitti

[4] The [illegible] London: [illegible]

some of the psychic manifestations of the neuroses will some day be explained in terms of neuro-physiology, the author felt himself constrained to adopt the psychological method of approach as the only one to offer an understanding of the neuroses. As he himself has said in the chapter referred to, "It is fruitless to discuss an obsession in terms of chemistry, or a hysterical phobia in terms of physics. As well discuss the sublime beauty of the Sistine Madonna in terms of aniline dyes, or the tragic conflict of Hamlet in terms of radio-activity!"

The present volume consists of a psycho-analytic, that is to say, Freudian, description of the neuroses; and the Freudian classification has been followed throughout. Neurological and endocrinological views as to etiology are also referred to in order to shed further light on the complex causation of the neuroses and to serve as a comparison with the psycho-analytic method. In the introductory chapters the author discusses the history of psychiatry and the development of psychopathology. The chapters which follow are devoted to the description of mental mechanisms, the etiology of the neuroses, their classification, clinical manifestation, their diagnosis, course, prognosis, and treatment. A short chapter is appended on taking a psychiatric and neurological history and making a mental examination. Two chapters, one on "General intelligence mental level and the psychoneuroses," and the other on "Psychometric tests," have been contributed by Dr. David Wechsler, the author's brother.

Professor Wechsler's book may be commended to all who accept the Freudian standpoint, and may induce others to re-examine their theories in the light of this.

THE NURSING OF INFECTIOUS DISEASES.

The little book entitled *Communicable Diseases for Nurses and Mothers*,[5] by Dr. Albert G. Bower and Miss Edith B. Pilant, is intended for the use of student nurses and mothers in the home, particularly in communities where skilled assistance is lacking. The diseases considered include all those named in the annual report of the Committee of the American Public Health Association on "Standard Regulations for the Control of Communicable Diseases." The forty-two diseases considered include not only the acute infectious disorders which are usually sent to isolation hospitals, but also venereal diseases, malaria, tularaemia, Rocky Mountain spotted fever, and yellow fever. The account of the various diseases is preceded by chapters dealing with the care of communicable diseases in private houses and in hospital, with details as to barrier nursing and ward management. The authors rightly emphasize the fact that aseptic technique is as important in dealing with infectious diseases as it is in the domain of surgery, though the fact does not appear to be sufficiently realized or enforced.

The work on the *Nursing Care of Communicable Diseases*[6] by Mary Elizabeth Pillsbury, which is the latest addition to Lippincott's *Nursing Manuals*, is divided into two unequal parts. In the first, which consists of seven chapters, the writer discusses the causal organism, modes of infection, measures of control of disease (special emphasis being laid upon the part played by the nurse), resistance to disease, and the various modes of prophylaxis and control. The second part, which forms the bulk of the work, is devoted to a consideration of the forty-two diseases listed by the United States Public Health Service as communicable, as well as six others—namely, colds, impetigo contagiosa, erysipelas, ringworm, scabies, and Vincent's angina.

Both books are written in a clear and concise style, and are not only admirably suited for the class of readers for whom they are intended, but contain details of nursing with which every medical practitioner should be familiar. Another work on the same subject,[7] by Dr. Eustace Thorp,

[5] *Communicable Diseases for Nurses and Mothers.* By Albert G. Bower, M.D., and Edith B. Pilant, R.N. Philadelphia and London: W. B. Saunders Company. 1929. (Post 8vo, pp. 327; 34 figures. 14s. net.)

[6] *Nursing Care of Communicable Diseases.* By Mary Elizabeth Pillsbury, B.S., R.N., M.A. London: J. B. Lippincott Company. 1929. (5½ × 8½, pp. 463; 116 figures. 12s. 6d. net.)

[7] *Infectious Diseases for Nurses.* By Eustace Thorp, O.B.E., M.B., B.Ch. London: Baillière, Tindall and Cox. 1929. (Cr. 8vo, pp. viii + 154. 5s. net.)

is written by one who is specially fitted for the task in his capacity of visiting medical officer to the Sunderland Borough Sanatorium for Infectious Diseases and Tuberculosis, and examiner in fevers to the General Nursing Council. This little book contains a clear and concise account of the diseases nursed in fever hospitals, including tuberculosis and venereal disorders.

NOTES ON BOOKS.

An Introduction to Pharmacology and Therapeutics,[8] by Professor J. A. GUNN, is a short book of about 200 pages, which presents the essential facts of elementary pharmacology. The author explains that his purpose here is to provide the medical student with a book that he can read in vacation before attending lectures in the subject. The author has evidently spent a great deal of time on the work, and has managed to present his subject in this brief form by exercising a very rigorous selection of material. At the same time, he has avoided making the book a bare catalogue of facts, and the volume constitutes an easily read introduction to the subject, and therefore should serve its purpose very well.

The seventh edition of *Landmarks and Surface Markings of the Human Body*,[9] by Mr. L. BATHE RAWLING, is similar in every respect to the sixth edition, reviewed in our columns on December 13th, 1924 (p. 1120), except that five new figures have been substituted for those illustrating the surface markings of the foot and ankle. The author in his preface writes: "The continued popularity of this book, first published in 1904, is sufficient proof that it fills a gap in the books on medical education." With this comment we are in full agreement.

Dr. LEWIS E. HERTSLET is a firm believer in the value of air and sun baths for the maintenance of health and the prevention and cure of disease. In his book, *Skin: Its Uses in Six Phases*,[10] he instructs the lay reader in the importance of the skin as a medium through which the air and the radiations from the sun produce their beneficial effects, and gives some account of other ways in which the skin may serve to regulate the health of the body. He writes with vigour and enthusiasm, and succeeds in crowding within a relatively small compass a great deal of interesting material bearing directly and indirectly on his main theme. The work is illustrated with eight well-produced photographs.

Dr. A. R. FRIEL has published a small book on chronic otorrhoea,[11] with special reference to the use of zinc ionization in the treatment of selected cases. The first part deals with the role of the electric current and zinc ions in the treatment of septic surfaces; the second with conditions in the ear in chronic otorrhoea and the technique of treatment by ionization; and the third with the organization of aural clinics, with special reference to the treatment of chronic suppuration of the middle ear in school children. The book is clearly illustrated with reproductions from line drawings.

In *La Pratique Psychiatrique*,[12] by Professor LAIGNEL-LAVASTINE, Dr. A. BARBE, and Dr. DELMAS, the increasing importance of some knowledge of psychiatry in general practice is emphasized, so that the general practitioner may be able to treat not only incipient cases of the severer kinds of mental disease, but also those neuroses which underlie many of the minor ailments so prevalent in these days. The anatomical, physiological, and psychical causes of the different mental diseases are discussed from a very up-to-date point of view, and some of the mental after-effects of the war are well described. The forensic portion is interesting though chiefly applicable to France. The mental effect of workmen's compensation with regard to prognosis is clearly set out. The fact that fifteen years after the French law permitted intoxicants to be sold more freely there was a sudden great increase in the number of juvenile criminals gives food for thought. The authors insist on the importance of prophylactic treatment for the improvement of the mental health of the public, especially in connexion with syphilis and alcohol.

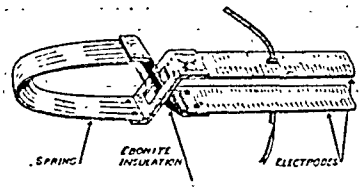
PREPARATIONS AND APPLIANCES.

AN APPLIANCE FOR TREATING ANTERIOR URETHRAL LESIONS BY DIATHERMY.

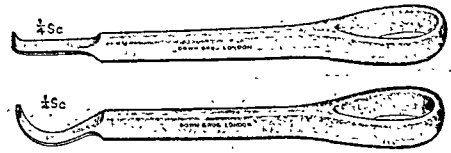
DR. F. J. T. BOWIE (Aberdeen) writes: I desire to introduce an apparatus designed for the treatment, by diathermy, of chronic infections of glands and follicles in the penile urethra in chronic gonorrhoea. It consists of two electrodes, each five inches long by three-quarters of an inch broad; they are slightly curved from side to side, with the concavities opposed to each other, and are connected by crossed insulating material



to a spring. The whole apparatus resembles, therefore, a pair of crossed-action forceps, the action of the spring being to keep the blades (electrodes) pressed together. The electrodes are opened out by compressing the spring; they are placed, one ventrally and the other dorsally, over the whole length of the penis, and are then allowed to close on the organ, thus collapsing the urethra into a flat tube between them. The diathermy current is turned on, and, passing through the whole thickness of the penis, treats the urethra *en route*. Since the walls of the urethra are flattened out dorsi-ventrally, the associated glands and follicles are spread out in a position which ensures a maximum effect from the current. This method of treatment of chronic folliculitis and littritis has given very gratifying results, obstinate cases yielding readily when all other methods have failed to ensure absolute cure; it has been used now long enough to warrant its use as a routine. I am indebted to Dr. J. F. Christie for permission to publish this description.

RASPATORIES FOR THE OPERATIVE TREATMENT OF FRACTURES.

Major MEURICE SINCLAIR, R.A.M.C. (ret.) (London), writes: These instruments are designed primarily for lifting the periosteum and young callus, together with the soft structures, from (1) the flat surface of bones; (2) the cylindrical surface of bones. They may also be used to retract the elevated tissues during a bone operation. Both have a periosteal cutting blade, a smooth oval shaft, and fenestrated handles, which give the operator a firmer hold. The blade of one raspatory is straight, with a square and slightly curled-up end, while the other is curved throughout, with a somewhat pointed extremity. When operating on the left femur and the periosteum or callus has been incised to the whole length of the cut, it is comparatively simple to pass the blade of the curved raspatory under the upper fragment with the shaft and handle projecting out of the wound and nearly at right angles to the bone. The operator stands with his left side against the table, and faces the patient's left shoulder; by grasping the



handle of the jutting-out instrument with the right hand, and hooking the fingers of the left under the shaft, he is able to keep the blade in close contact with the bone by the firm, upward lift. This force is reversed when the instrument is used to clear the anterior convexity of the bone. When the upper end of the lower fragment is being attended to it is advantageous to use the left hand in a pronated position and employ a pressing force in the direction of the cleavage. The hold of the left fingers gives the purchase required for the longitudinal pull or push; at other times it acts as a useful fulcrum. These movements alternating with one another, together with a slight, constant rocking motion of the right hand, will very readily and neatly detach young callus and the strong fibrous attachments from the roughened ridges of the linea aspera. The straight raspatory is used much in the same way. It may also be used in a deep wound to hold back the tense strata of tissues from the immediate neighbourhood of the eyelet of the wire-introducer, and thus allow the assistant to pass the wire safely into its opening without delay. Subsequently it permits the encircling of the fragments of bone in a very ready manner, as described in the *British Medical Journal*, August 3rd (p. 207). These instruments are made for me by Messrs. Down Bros., St. Thomas's Street, S.E.1.

MOTOR CARS FOR 1930.

THE OLYMPIA SHOW: A FINAL REVIEW.

[FROM OUR MOTORING CORRESPONDENT.]

THE 1929 Olympia Show, which closes to-day (Saturday, October 26th), has continued to attract considerable attention. A year ago there was a good deal of talk of changing the exhibition from an annual to at most a biennial event, owing to the heavy financial burden it thrusts on exhibitors, and the view was expressed in these columns that if the show was to continue yearly and the exhibitors to secure an adequate return for their outlay, the question of the overcrowding of the stands by motor agents and their representatives from all parts of the country would have to be dealt with. The complaints that inspection of the cars was considerably obstructed, if not actually prevented, by the presence of an unnecessarily large number of salesmen and traders, indeed, became so general that the organizers of the exhibition were compelled to take action. Thus, during the show now closing, a limit was put on the number of sales assistants permitted on the car stands, the authorized persons wearing a badge to identify them with the particular car with which they are associated. At the time of writing it is not possible to estimate completely what effect the new arrangement will have had on the total attendance, but in the first few days of the show it was evident that the stands were less crowded than in past years and, except perhaps at those of such popular makes of cars as the Austin, Morris, Singer, and Swift, it was consequently possible to examine the cars and chassis with greater ease and comfort. Even although the attendance figures may not establish a record, any decline in the total will not represent a diminution of public interest, but merely a reduction in the number of "clicks" of the turnstiles through which the trade representatives have in altogether unnecessary numbers formerly passed.

Safety Motoring.

The keynote of the show is undoubtedly to be found in the consideration given to the requirements of the owner-driver. Nearly every new device, every new development, and every change in design has been introduced with a view to making motoring safer and more comfortable, and the owning of a car as little troublesome as possible. Centralized chassis lubrication, chromium plating, easy gear-changing arrangements, and servo devices to assist in the application of the brakes are all adding their quota in this direction. The safety factor in motoring is also becoming increasingly important, and for that reason the tendency to standardize unsplinterable glass and to build cars with a slightly lower frame and lower centre of gravity is to be welcomed.

Since the advent of four wheel brakes, and a growing practice of manufacturers to link up the hand lever with the shoes of the rear wheel brakes, there has been some doubt of the legal position, the motoring regulations having hitherto required that cars shall be fitted with two independent brakes. On the eve of the show the Ministry of Transport issued an Amendment Order which brings the regulations up to date and makes the position quite clear. Under the new rules, in the case of cars with four wheel brakes, two entirely independent brakes are not in future to be insisted upon. There must, however, be two independent means of brake operation, and even in the case of cars fitted with servo-actuated brakes one of the methods of operation must be direct. Also, in the case of brake failure, the construction must be such that brakes on two wheels are always available; furthermore, one of the brake controls must be so arranged that it can be secured in the "on" position when a car is left unattended.

A WIDE CHOICE OF CARS.

There are few if any countries in the world in which motorists have so wide a selection of cars as Great Britain. The list of the different makes extends to well over one hundred, the number being at least tripled, if not quadrupled, when the various models of each manufacturer are taken into account. It is therefore obviously impossible to refer to the productions of all the different makers; the writer, in the cars mentioned last week and in those referred to below, has, however, endeavoured to select those suitable for doctors' use.

Crossleys and Rovers.

Crossley Motors, Ltd., are continuing their 15.7 h.p. and 20.9 h.p. six-cylinder cars with only detail changes in the chassis; the bodywork has, however, been greatly improved, some very attractive designs being available. The Rover Company, in addition to their well-known 10–25 h.p. four-cylinder and two-litre six-cylinder cars, have added to the range a new light "six," with a power unit similar to the two-litre model, but with a smaller and lighter chassis; it is mainly intended, however, for sporting motorists' use. Some very elegant body designs are included in the Rover range, which include, both for the 10–25 h.p. and two-litre chassis, a saloon with a folding roof.

The Fiat.

Among the most widely used of Italian-built cars is the Fiat. The makers are nowadays largely concentrating their attention on six-cylinder vehicles, but although the 9 h.p. is the only "four" left in the construction programme, it is a useful little vehicle and a favourite with many doctors. Several new designs of both two- and four-seated bodies have been introduced, notably a fixed-head coupé at £235 and a fabric four-door saloon at £250. For those desiring a larger and more powerful car there is a choice of 17–50 h.p., 18–55 h.p., and 20–70 h.p. six-cylinder models. The 18–55 h.p. is the latest addition to the Fiat list, both chassis and bodywork being on thoroughly modern lines. The five-seated coach-built saloon is priced at £395, or only £20 more than the 17–50 h.p. model.

Some Popular American Models.

Among the popular American and Canadian cars in this country is the Buick, which is available with six-cylinder engines of two different capacities, the cheapest, with saloon body, being listed at £485. Among the detail improvements of the latest models are lower-built bodies, longer wheelbase, servo-operated brakes, thermostatically controlled radiator shutters, Lovejoy shock absorbers, and many new accessories. General Motors have also introduced a new popular-priced car known as the Marquette, the six-cylinder engine of which is not quite so powerful as that of the Buick. The car, however, possesses many good features, and although it has only been on the market a short time is already being well spoken of. Another popular and widely used American car is the Essex, which, although fitted with a six-cylinder engine carrying a £19 annual tax, is available at prices ranging from £250 for the coach or two-door saloon to a convertible coupé with a dickey seat or a five-seated town sedan at £295. The latest models embody many detail improvements both in the chassis and the bodywork, noteworthy features being a roller-bearing steering gear and easily adjusted brakes. Like the majority of next year's cars, all bright parts are chromium-plated.

A New-Type Radiator on Renault Cars.

A French firm that is steadily changing over from four- to six-cylinder vehicles is the Renault Company. Of the "fours" only the 14–45 h.p. model is retained, while there are now two six-cylinder cars of respectively 12.5 and 21 h.p., a five-seated coach-built saloon of the lower power costing £310. The main change in Renault cars is in the radiator. For many years, unlike the majority of cars, this has been located at the dashboard end of the engine. In the latest models it is at the front; it is, however, inclined rearwards and concealed by the bonnet, the front of which is provided with shutters.

Two Coventry-built Cars.

Those doctors who use the Standard cars will be interested to learn that the makers are continuing to concentrate on but two chassis models—the 8 h.p. four-cylinder and the six-cylinder. Neither of them shows important mechanical changes, but there are many improvements in the bodywork, the variety of which has also been increased. In this connexion, too, it is interesting to note that, despite an increasing vogue of cars with brightly

painted bodywork, the Standard Company have found it desirable to add one in a quiet combination of black and brown to the range of 9 h.p. vehicles. This model is made in two lengths of wheelbase, at prices ranging for saloons from £185 to £250, the latter being the "Teignmouth" special fabric saloon, which has wire wheels, safety glass windscreen and windows, bumpers, chromium-plating, and many additional accessories. The vehicle which is, however, likely to appeal to many doctors is the 15 h.p. six-cylinder Standard, at prices ranging from £325 to £365. As with the 9 h.p., the chassis is available in two lengths of wheelbase, the longer one, which is known as the "Envoy," being fitted with very roomy bodies. The details, too, have been greatly improved, the lamp control switches, the head-lamp dipping controls, and horn switch, for example, being now, in addition to the throttle and ignition levers, neatly grouped on the steering column. Leather is used for the upholstery, while the interior finish generally has been improved. It may be added that all the Standard Company's saloons can be fitted with the Stanlite sliding roof.

Among the cars in which radical alterations have been effected are those of the Swift Company. Only one type of chassis is being made—10 h.p. four-cylinder—which, however, is being produced with a wide variety of bodywork, at prices ranging between £235 and £295. Among the chassis alterations to which attention may be drawn are an entirely new design of chromium-plated radiator, the adoption of semi-elliptic springs with shock absorbers at both front and rear, a lower centre of gravity, and "one-shot" chassis lubrication. Among the models suitable for doctors' use are a drop-head coupé, a "foursome" coupé—a fixed head car with seats for two at the front and two occasional seats at the rear—and the "Migrant" four-seated four-door saloon, both the latter being fitted with Pytchley sliding roofs so that they may be used in closed or open form.

The Wolseley Range.

A make of car that has long held a good reputation for reliability among members of the medical profession is the Wolseley. The range of choice is a very wide one, embracing as it does 12–32 h.p. four-cylinder, 16–45 h.p. and 21–60 h.p. six-cylinder, and a 32–80 h.p. eight-cylinder. So far as chassis are concerned the changes are confined to matters of detail, the main Wolseley departure for 1930 being the introduction, in addition to the standard vehicles, of a range of de luxe models known as the "County" in both 16–45 h.p. and 20–60 h.p. forms. Among the fittings which justify the term "de luxe" are chromium-plating, dash-controlled radiator shutters, electrically operated dipping headlights, safety glass, two spare wheels, and upholstery and internal fittings of special quality. While the 12–32 h.p. four-cylinder saloon at £345 will meet the requirements of many doctors, there are no doubt some to whom the 16–45 h.p. six-cylinder saloon with four or six lights, at £405, will appeal, the "County" de luxe models costing an additional £45.

More British Six-cylinder Cars.

Among the makers of British cars who are continuing their previous models unchanged except for detail modifications in both chassis and bodywork are the Sunbeam, Clement-Talbot, and Vauxhall companies. The first-named concern is building six-cylinder cars in three sizes—16 h.p., 20 h.p., and 25 h.p. The Talbots are confined to a single 14–45 h.p. chassis model fitted, however, with a wide selection of bodywork, notable among which is a three-quarter coupé-cabriolet, at £465. The Vauxhall Company are also concentrating on a single chassis type—a 20–60 h.p. six-cylinder model which embodies many interesting features.

In view of the increasing popularity of six-cylinder cars it is worth while remembering that one of the first to realize the advantage of six cylinders over four was Mr. S. F. Edge, who, in the early days, was closely connected with the Napier Company, whose energies to-day are entirely devoted to the production of aeroplane engines. For some years past Mr. Edge has been at the head of A.C. Cars, Ltd., whose productions are confined to six-cylinder vehicles bearing the name Acedes. For the 1930 season the company has brought out a new and larger model known as the Acedes Magna, it being fitted with an engine which, although rated at only 16 h.p., is capable of developing up to 60 h.p. A feature of the car is that the gearbox is located above and in front of the differential casing, with which it forms a unit. The four wheel brakes are of the Lockheed hydraulic type, while the steering gear is of a newly patented form notable for the simplicity of the adjustment for wear and backlash. The Acedes 16–40 h.p. models range in price from £350 to £395, and the new Magna models from £475 to £495.

Prices for 1930.

In the preceding articles of this series the various cars of 1930 have been mainly analysed from the point of view of the number of cylinders and that of the chassis details; the matter of prices has only been briefly alluded to. Price being, however, an important consideration, it may be well to look at the new models a little more closely from this aspect.

Taking vehicles with saloon bodies as being the most popular type at the present time, there are only three makes below £150—the Austin Seven, the Morris Minor, and the two-cylinder Jowett, all being of the miniature type yet well able to give good service. Between £151 and £200 there is a choice of nine makes, all, with a single exception, being fitted with four-cylinder engines. At the lower end of the section are the Singer Junior and the Triumph Super-seven, while towards the £200 limit chief attention centres on the 9 h.p. Standard, the 11.9 h.p. Morris-Cowley, and the 14.9 h.p. Ford, the latter, although not seen at Olympia, being, in its modern form, an increasingly popular model. As the price increases, so does, up to a point, the variety of choice. Thus, from £201 to £250 there is a selection of about eight cars, only three of them, however, having six-cylinder engines—the Essex, Erskine, and Chevrolet, the latter being somewhat handicapped in this country by its annual tax of £27. Of four-cylinder models, the best known are the Fiat and the Willys-Overland Whippet. In the £251–£300 category there are a dozen four-cylinder and half that number of six-cylinder models to choose from. Chief among the "fours" are the Citroën, Humber, Swift, and Rover, while among the popular "sixes" are the Armstrong-Siddeley, Citroën, Morris-Oxford, Renault, and Singer. Several excellent cars are available in the £301–£350 group; the majority have six-cylinder engines, among the more prominent being the 15 h.p. Standard and the Singer Super-six. What four-cylinder vehicles there are in this section are, however, well-tried products, such as the Austin Twelve and the 12–32 h.p. Wolseley. Taking the £351–£400 cars as being the outside limit of the average medical man, the six-cylinder type is in this case in the majority, the range including the 16–40 h.p. Acedes, the 15 h.p. Armstrong-Siddeley, the Austin Sixteen, the Chrysler, Fiat, Morris-Isis, the 23.4 h.p. Nash, the 21 h.p. Renault, and the 14 h.p. Riley. There is one American eight-cylinder car in the group at £395, but the cheapest British "eight" is the Hillman at £445.

A Look Round the Galleries.

Although the majority of cars are now turned out so completely equipped in the way of lamps, horns, and a wide variety of accessories that there would hardly appear to be room for any further additions, yet a walk round the galleries at Olympia always reveals many interesting and useful devices. Mention has already been made of the many radiator "cosies," garage stoves, and other appliances for winter motoring use. To these may be added, lest the fine summer be again followed by a severe winter, the Parsons non-skid chain attachment for tyres, to facilitate car driving over snow-covered roads, the device being one the efficiency of which has long been recognized.

The headlamp dazzle problem, also previously alluded to, is being attacked in two main ways. On the one hand there are numerous devices fitted in conjunction with headlamps to prevent any dazzling of the eyes of the drivers of oncoming vehicles, and, on the other, a number of coloured celluloid and glass attachments to the windscreens

that overcome the dazzling effect of powerful fixed headlights. Among the first-mentioned devices worthy of notice are those of Barker and Company, which is made in three forms—a straight dipper, a dip and one-way turn, and a dip and a right and left swivel. The Lucas dipping reflector arrangement also appears to be very effective. Included in the range of lamp exhibits are several specially designed for use in foggy weather as well as one or two attachments for the fronts of headlights, which are claimed to be able so to diffuse the light that it will penetrate fog.

There is, of course, the usual range of exhibits of magnetos and coil ignition devices, while among the many displays of sparking plugs is that of Lodge Plugs, Ltd., a tribute to whose manufactures is afforded by the fact that their plugs were used on the engine of the aeroplane which proved the winner of the recent Schneider Trophy contest. Recent research by the Lodge Company in connexion with plugs for aircraft use has resulted in the discovery of certain improvements both in materials and in methods of construction, some of which have been embodied in the plugs for use on cars. In an earlier article reference was made to the necessity for devoting some attention to the lighting equipment, and particularly to the battery on which so much depends, the more so in these days when the accumulators are being relied upon to supply current for ignition as well as for the engine starting and car lighting. Among the firms specializing on battery manufacture are Oldham's, Lucas, Hart, P. and R., Exide, Tungstone, and Vandervells. Whichever make is chosen, the main point to bear in mind, just as with the car itself, is not so much the actual first cost as the degree of service the article will render.

Most of the gallery exhibitors are wholesale only, but among the retailers of accessories are Dunhills, Ltd., and A. W. Gamage, Ltd. At the stand of the last-named firm, in addition to all the latest "gadgets," there are some excellent driving gloves and rugs. At Gamage's stand, too, are some useful small cases of spare lamp bulbs, one of which should always be carried by country practitioners who have much night driving to do, as there is nothing more disturbing than a lamp failure in the dark with no spare bulb at hand.

So wide is the range of useful accessories that it is possible only to mention the many improved forms of jacks, the useful preparations for stopping leaks in radiators, and the many pastes and liquids now available for maintaining the clean and fresh appearance of the paintwork and metal fittings of cars. A useful device, of which several patterns are now available, is a petrol filter, the outer casing of which is of glass, so that it can be seen at a glance whether the filter needs cleaning out, many engine stoppages on the road in the past having been traced to choked-up filters. Although more numerous than a year ago, cars fitted with "one-shot" chassis lubricating arrangements are still in the minority, so that a good deal of interest is taken in the special pressure oil and grease-feeding guns now available, while those who know what a messy job the filling of grease guns can be will appreciate the grease cartridges now being marketed, which are so made that they can be quickly and cleanly introduced into grease-gun barrels.

The Tyre Section.

Motor tyres have so greatly been improved, from the point of view of their wearing qualities, since the war that it is not surprising there are no striking departures to be found in the tyre section of the exhibition. Here and there new tread designs have been introduced to render tyres more proof against skidding, but, this apart, the most noticeable feature is the production in this country of many of the makes, such as the Michelin, Goodrich, and Pirelli, that were formerly imported. Although it is hardly likely to appeal to doctors, who cannot afford to economize in the matter of tyres, it may be mentioned that the Dunlop Company, in addition to their Dunlop Fort tyres, now have a cheaper variety in the Clipper. It may be noted, too, that the Avon tyres have been improved, both as regards the anti-skid tread design and the strengthening of the walls of the covers.

C. J. W.

CHARTERED SOCIETY OF MASSAGE AND MEDICAL GYMNASTICS.

THE Chartered Society of Massage and Medical Gymnastics, which has been holding a series of conferences in the Great Hall of the British Medical Association's House in London, assembled for its first annual dinner, on October 16th, at the Café Royal. Mr. R. C. ELMSLIE presided over a large company of members and guests; the latter included Sir Farquhar Buzzard, Sir James Purves-Stewart, Sir Henry Gauvain, Sir Arthur Stanley, Dr. Jane Walker, Dr. Catherine Chisholm, and Dr. Alfred Cox, Medical Secretary of the British Medical Association.

In responding to the toast of the society's health, which was proposed by Professor WINIFRED CULLIS, Mr. ELMSLIE referred regretfully to the absence of the chairman of the council, Sir Cooper Perry, who, he said, had been foremost in the efforts to obtain a charter, and whose counsel and ripe experience had always been at the society's service. Massage, Mr. Elmslie continued, was an old and widespread remedy, almost as ancient as medicine itself, though medical gymnastics might be said to be only one hundred years old, dating from the time when Ling founded his school at Stockholm. It was not until the latter part of the last century, however, that massage became a scientific treatment, and its practice on any considerable scale in this country was still more recent. When he himself was a student at St. Bartholomew's, shortly before 1900, the entire massage and exercise treatment at that hospital was carried out by one masseuse and one porter, both of whom held the certificates of the then newly incorporated society. It was about 1894 that a society of trained masseuses was founded by ten practitioners of the art, only one of whom (Miss Paget) was still with them. After six years, with 200 certificate holders, the society became incorporated, and in 1905 the articles of incorporation were extended in order that the society's examination might include male candidates, after which time regular examinations of candidates from the naval and military hospitals were held. On the outbreak of war the late Mrs. Almeric Paget founded a corps of masseuses, almost all of whom were members of the incorporated society, for employment by the War Office for work in the military hospitals, and from this developed the military massage service and later the pensions massage service, both still existing, although now having greatly reduced numbers. The charter was granted in 1920, and the society had obtained the permission of the Privy Council for its members to use the title "chartered masseur" or "chartered masseuse." The membership at the present time was 7,276, of whom 470 were men. Mr. Elmslie claimed for the society that it was the greatest organization in the world for physical treatment, and that massage was better organized and regulated in this country than in any other. The society had been fortunate in obtaining the assistance of members of the medical profession. It was sometimes complained that the medical profession did not utilize the services of the society to the full, but it had to be remembered that the growth of the society had been very rapid, and that there were still many physicians and surgeons in practice who were entirely unfamiliar with the value of physical treatment on modern lines. A great deal had to be done in the way of educating the medical profession. Among other recent developments he mentioned the new examination in medical diathermy and light therapy, and that the Society of Apothecaries had established a roll of biophysical assistants, persons qualified to administer these treatments under the direction of a member of the medical profession. Mr. Elmslie closed with the remark that massage and physical methods were of such value that they ought to constitute an additional benefit under the Insurance Acts.

In reply to the toast of "The Guests," Sir FARQUHAR BUZZARD confessed that in the course of his medical career he had probably prescribed massage less than any medical man or woman in that room. Recently, in connexion with an address of his, he had been "rapped on the knuckles" for being too pessimistic, but he was not really pessimistic about massage, and certainly not about medical gymnastics, especially after reading an excellent article in the society's journal on the treatment of patients suffering from the terrible after-effects of encephalitis lythargica. Dr. JANE WALKER also replied to the toast in a speech recounting some amusing experiences.

PSYCHIATRIC UNITS IN PUBLIC HOSPITALS.

BY

ALAN RANDLE, *M.C.*, M.D.Lond.,

MEDICAL SUPERINTENDENT, ST. PETER'S HOSPITAL, WHITECHAPEL.

The subject of the treatment of early mental disorder has deservedly received much attention in late years; it admittedly bristles with difficulties, which arise from many causes, some of them capable, in my opinion, of considerable amelioration, even under existing conditions of legislation. It is with a view to describing an experiment now being made in London that I am writing this article.

Most of the preliminary treatment of mental cases in London is carried on through the machinery of the Poor Law, by medical officers and nurses of the observation wards of the workhouses. Here the patients arrive very often hostile and refractory, having betrayed their affliction sufficiently to bring them within the arm of the law, either through police channels or under the statutory detention order of a relieving officer. On arrival at these observation wards, often unsatisfactory in structure and staffing, they must be examined by a justice and a doctor with a view to certification or discharge; criticism has been levelled against this system from many angles, among the more serious charges being lack of skill in diagnosis and treatment, and in the nursing and handling of the patients.

From the point of view of the general public health the problem is of outstanding interest, since the mental breakdown is often the concomitant or even the precursor of a physical breakdown. The apparently general increase of nervous disorders should be regarded as a warning to us to examine the machinery of our civilization with great care —especially in so far as it tends to produce exhaustion of nervous powers—and to take measures to counteract their influence at every turn. It has been my good fortune to have to cope with a corner of the problem in circumstances of considerable difficulty; it may therefore be truly claimed that if some success has attended this effort, then the beginnings of a path have been found, and in more favourable circumstances greater success should be attained. The scheme has been considered promising enough to be recommended for adoption by the London County Council when it takes over control in April, 1930, and so perhaps it is worth while setting out in some detail.

Object of the Scheme.

The scheme aims at bringing all the suspected incipient mental disorder in an area in touch with a unit comprising in- and out-patient departments, and situated in a hospital which deals with physical ailments. The unit must be of such a standard as to command the confidence of the public, and patients should be willing to resort to it without always having to be driven to it. The best specialist advice would be obtainable, and also the most *modern* methods of treatment; there would be special facilities for the most kindly and helpful inquiries to be made with a view to cutting the illness short and preventing its recurrence. The activity of this unit should not, in my opinion, so heavily preponderate over the rest of the work of the hospital as to lead to its being more than a large special department. Within its scope should be included:

1. Any type of organic nervous disorder.
2. Any type of functional nervous disorder.
3. Disorders of conduct in children.
4. Incipient mental disorder in adults who attend voluntarily.
5. Cases under statutory orders for detention and examination.

It was the present inadequate provision for this last category which led to my investigations of lines of possible advance. The subject is rather complicated legally, but it will never present great difficulties for those able to make adequate provision privately. The ordinary poorer citizen, however, who shows signs of mental disorder is removed to an observation ward in what is legally a workhouse, and in that ward grave decisions have to be arrived at which affect his future liberty and treatment. Certification may be called for in order to protect the patient and the public, but no one can deny that the fact of certification is not helpful to a citizen subsequent to recovery, whereas a stay of a few weeks at a nerve clinic may actually stamp an individual as being of a superior order of intelligence. Why should not the poor be allowed the luxury of a nervous breakdown occasionally without the stigma of certification?

For these observation wards there is often no skilled nursing available; there are no facilities for diagnosis or treatment on a modern scale; there is a financial reward for transferring cases to a mental hospital, and often the governing idea is to send patients on to a mental hospital at the earliest possible moment, where skilled treatment will be available in good surroundings. Any critic who saw my observation wards might think this theory was correct, but the patients and friends very seldom take this view, having, for various reasons, an intense dislike of the fact of certification.

How the Scheme may be Carried Out.

If we agree that prevention of certification in a case likely to recover quickly is a desirable end, then the path to reform of the existing conditions becomes fairly clear. First of all there must be a consultant of standing who will give an opinion as to which cases should be certified, which discharged, and which detained for treatment. To do this satisfactorily necessitates having a fairly large unit of beds at one's command—say 150 to 200. The advantage of this will be the possibility of classification in the admission stage, with segregation of the noisy or objectionable patient; these patients often quickly recover, but the inexorable demand of the welfare of the *majority* will lead to certification in the absence of isolation accommodation.

Site.—These wards should be in an institution which is situated conveniently for the district in which the sickness occurs. As in the case of any other acute illness, mental disorder is best treated near home and friends, and the question of transfer to country surroundings should be left until the acute stage is over. This opinion may arouse hostile criticism, but it is based on the observation of several hundred cases over a period of years, and the expressed views of numerous relatives, friends, and the patients themselves. Mental patients often travel badly, and the shorter the journey before they come under skilled supervision the better.

Structure.—The observation wards should give facilities for the seclusion of individual patients on a scale not yet adequately worked out, but possibly of one for every eight to ten cases. In a unit of 80 beds this would mean seclusion accommodation for at least eight cases. The ward decoration should be cheerful, and there should be an opportunity for open-air treatment. The recovery wards should be similarly provided with small wards, since to these will resort the patients who are not under statutory orders for detention, but who urgently require rest and treatment.

The Scheme in Operation.

The following is a brief description of the actual working of the scheme at St. Peter's Hospital. This is a Poor Law institution, containing about 500 beds, in the congested area of Whitechapel; it caters for a poor but hard-working conglomeration of mixed races. Of the 500 beds, 31 are in the observation wards (male and female), and a varying number, up to about 30, in recovery wards for both sexes, and situated above the observation wards.

Patients are admitted on statutory orders of detention from the whole of Stepney, and these orders can be prolonged on a medical officer's certificate for a further fourteen days. This is a valuable power, which exists only in the hands of the Poor Law doctor, and its lack would hamper the activity of any but a statutory authority undertaking this work. The London County Council will

be the Poor Law authority as well as the hospital authority, so quite obviously the possibilities for improved work on the psychiatric side are much enhanced.

One medical officer out of the six comprising the resident staff deals with the work of the special wards; he writes the notes for the specialist's visit and arranges for any pathological examinations. He prepares notes in duplicate for sending with any patient transferred to another institution; in this way he is able to maintain a continuity of information about the patient's illness, which is of great use at the other end of the journey. The duplicate is filed, and to it is added any further information obtained if the patient returns. This medical officer becomes skilled in diagnosis and treatment, even if he is not so at first, for every patient admitted is seen by the specialist, who visits once a week; these visits could no doubt with advantage be more frequent, but there is always the question of remuneration and responsibility. The conditions are not like those of a general hospital, where the beds are in charge of a specialist. Under the Poor Law orders the beds are in charge of the resident medical officer, the specialist being the adviser, and the responsibility of the medical officer in charge is underlined in all orders, written and oral. The medical officer attached to the observation wards for purposes of admitting and relief duties shares the general work of the hospital, and so keeps in touch with it.

Nursing.—The nursing is supervised on each side by the equivalent of a "sister," who holds the medico-psychological certificate; on the male side the whole staff is male. The nurses work an eight-hour day in these wards, but in the recovery and general wards the hours are a little longer. As many as possible hold the medico-psychological certificate or receive training in mental therapeutics. The recovery wards are supervised by specially trained or qualified "sisters," and working under them on the male side are male probationer nurses as well. Here I would point out that it is an advantage to have a male nurse *training school in conjunction with the scheme, since male* probationers can often be obtained with the medico-psychological certificate, and anxious to receive general training.

General Service.—In addition to the provision of special medical and nursing facilities, the fact that these patients are in a building in which the work of a general hospital is also going on enables every branch of specialist service and treatment to be brought to the patient's aid. Ophthalmological, otological, x-ray, dental, and other services are all available on the spot, and beds in appropriate wards can be obtained. Mental patients have often been transferred to general medical or surgical wards, with great advantage to themselves and no harm to others.

Out-patients.—An out-patient clinic has been established, and is open once a week. To this persons seeking advice can come on a doctor's recommendation, without having to pass a relieving officer; on the other hand, it caters for relief cases, or follow-up cases discharged from hospital. This clinic enables supervision to be continued, and the early help to be given which may avert later serious consequences. The functions of such a clinic are capable of being developed in many directions, but it is certainly not my purpose to have it regarded solely as the resort of the seeker after bottled knowledge.

Social.—An important part of the work is the maintenance of contact with friends and relatives. As soon as possible after admission the friends see the medical officer, give him an account of the illness and general history, and receive certain assurances about treatment and disposal which help to set their minds at rest. The day after the specialist's visit they can call again at 9.30 a.m., hear what his opinion is, and state any special wishes they have in the light of that opinion. Considerable elasticity is exercised in this area with regard to the discharge of patients to the care of friends, on condition that they sign a responsibility form; but no doubt every doctor must make his own standard of advice conform to that of a legal authority, having regard to the needs and creeds of the particular area he works in, and risking his patient as little as possible, but also paying some heed to the justifiable sympathies of public opinion.

In the following table I give a few statistics of observation ward cases.

	1921.	1922.	1923	1924.	1925.	1926	1927.	1928.
No. of cases admitted ...	151	142	158	147	169	345	5 5	517
Cases certified for mental hospita	80	82	83	87	105	176	249	232
Percentage certified (approximately)	53	58	53	59	62	51	45	4 8

These figures show a marked drop in the percentage certified consequent on the new policy adopted on centralization in 1926. On 500 cases a 10 per cent. saving of certification means a total of 50 persons a year benefiting by the result of early treatment.

I am indebted to the Stepney Guardians, to Dr. Mapother (the consultant), to Dr. Marian (my assistant medical officer), and, in fact, to the willing co-operation of all who have been brought in contact with the work, for being able to say that mental disorder can be approached like any other illness, and encouraging results be obtained. I can forward fuller statistics of the work to any persons specially interested.

VISIT OF JUGOSLAV DOCTORS TO LONDON.

THE party of over one hundred Jugoslav doctors now visiting London assembled on the morning of Saturday, October 19th, in the Barnes Hall of the Royal Society of Medicine, at 1, Wimpole Street. Short addresses of welcome were given by Sir William Hale-White and Sir James Berry on behalf of the Fellowship of Medicine and the Jugoslav Society of Great Britain respectively. Dr. Richard Burian, professor of physiology at Belgrade University, speaking in excellent English, made a graceful reply. He said that when his colleagues decided to visit this great city they were not only animated by the desire to see the vital centre of a large part of the world, and the capital of a nation which had contributed immensely to civilization, but they wanted above all to have contact with the leaders of British medical science and the British medical service.

Continuing, Professor Burian said: "We Jugoslavs are conscious of the fact that we have, individually and as a whole, very much to learn from the great British nation. Only some months ago our excellent Professor Bogdan Popovic gave us a beautiful lecture on this subject. This, the contact with you, is of inestimable value to the Jugoslav medical men, even so far as medicine is not concerned. However, its principal importance is on medical grounds. Our two medical faculties, of Belgrade and of Zagreb, are young and not quite settled, being founded in a country worn out by the war, and without proper traditions in medical teaching. But we are earnestly endeavouring to raise teaching and research, theory and practice, to a level equal to that existing in other civilized countries, and for these efforts of ours nothing can be more helpful than a close relation with the headquarters of British medicine. Therefore we hope that these relations will become more and more close and cordial, and that we shall have the pleasure of welcoming British medical men among us, although our medical institutions are only at the beginning of their development. A few days ago we had the privilege of seeing at Belgrade Dr. Leonard Findlay, the excellent professor of paediatrics at Glasgow, and to listen to his most interesting lecture. We should be happy if other representatives of British medical science would follow this example."

Professor Ainsworth Davis then showed Dr. Ronald Canti's cinematograph film of the cultivation of healthy and cancerous tissues under the microscope and the action of radium emanation upon them. This film had been lent by the British Empire Cancer Campaign, and was greatly appreciated by the audience. In the afternoon the visitors were entertained to tea at the Mansion House by the Lord Mayor of London.

On Sunday morning a large party made an excursion to Oxford, and in the afternoon a reception was given at the Legation in London by His Excellency the Jugoslavian Minister. Among the medical and other institutions visited on Monday was St. Thomas's Hospital, and in the evening the visitors were entertained by the Jugoslav Society of Great Britain at Crosby Hall, Chelsea, where they had an opportunity of meeting a number of prominent members of the medical profession in London.

British Medical Journal.

SATURDAY, OCTOBER 26TH, 1929.

PUBLIC CLEANSING IN LONDON.

"I am certain," said Mr. Arthur Greenwood, Minister of Health, in the course of a speech at the recent autumn dinner of the British Medical Association, "that in this country we shall never be in danger of a bureaucracy." The word "bureaucracy," it is clear, carries with it certain sinister implications; it is not what one may call an emotionally neutral word, but like many other words etymologically devoid of emotional significance, it has come by usage to acquire emotional accretions which have distorted or added to its original meaning. At present the word is understood to imply not only a method of government, but a hostile criticism of that method; indeed, an institution or a method of administration may be condemned simply by applying this epithet to it. The question "What's in a name?" it would therefore seem, cannot be adequately answered by the simple statement that "A rose by any other name would smell as sweet." Names may have their own dynamism, and not merely describe the things to which they are applied, but express or even determine our attitude towards them. The group mind has aptly expressed this psychological truth in the proverb, "Give a dog an ill name and hang him," and to this we may add: "Call an institution bureaucratic and condemn it." Etymologically, "bureaucracy" signifies government by bureaux, and the bureaucrat is a person who endeavours to concentrate administrative power in his own office. It is probable that persons and institutions to whom these names are applied will always be suspect in a world which values liberty above mere efficiency, and, in the long run, it is perhaps in the interest of good government that this should be so; but not less in the interest of good government is it worth remembering that such institutions and such persons may or may not, according to circumstances, work for the common good.

An extension of bureaucracy, though of bureaucracy to which everyone concerned with preventive medicine may give whole-hearted support, was predicted by the Minister of Health in the course of some remarks he made on October 14th to the Metropolitan Mayors Association on the subject of public cleansing in London, a service which he described as a scandal to the capital of the British Empire. "I am," he added, "speaking the naked truth when I use the word 'scandal.' Water and the collection and disposal of refuse mean more perhaps to national health than any other two factors. Until we have solved the great problem of public cleansing London will not have the right to hold up its head in the world. I am determined that the matter shall be settled, and that the councils shall settle it. The problem has to be solved somehow as a common problem, and not merely as one for each metropolitan borough." Some indication of the magnitude and the urgency of the problem was given in our leading article (April 20th p. 734) on the report by Mr. J. C. Dawes of an investigation into the public cleansing service in the administrative county of London.

It will be recalled that Mr. Dawes demonstrated the complete failure of the existing system whereby London's refuse is dealt with by twenty-nine separate cleansing authorities, and urged that a satisfactory service for what is in effect one compact area—in which he would include some, at any rate, of the districts outside the metropolis—could be provided only by a centralized scheme administered by a special body representative of all the sanitary authorities. Detailed criticism was directed against the crudity of the prevalent method of collecting refuse in vehicles of obsolete design, which, moving through the streets with their contents bulging over the tops, scatter dust through the windows of houses and into the eyes, noses, and mouths of the passers-by. The severest condemnation, however, was reserved for the present method of dealing with refuse, whereby boroughs indiscriminately send their rubbish into adjoining areas for disposal, and, above all, for the indefensible and unhygienic practice of dumping the crude refuse on London on the banks of the lower Thames. These riverside dumps are an offence to smell and sight; they are breeding-belts of flies and other insects, and the haunts of vermin. One of these dumps is no less than 90 ft. high, and its spontaneous combustion has generated clouds of smoke and a stench which have become intolerable to the inhabitants of neighbouring villages. There is no little irony in the fact that the outward pressure of London's increasing population, which should have driven people from the congested areas of central London into pleasant rural districts, is in fact forcing them nearer and nearer to insanitary areas overshadowed by mountains of festering muck.

In our issue of October 5th (p. 646) we recorded an interesting discussion on the situation disclosed in Mr. Dawes's report, which took place at a conference attended by representatives of the county councils of Middlesex, Essex, Buckinghamshire, Hertfordshire, and Kent. At this conference the following resolution was agreed to: "That in the opinion of this conference a local authority should not be permitted to deposit by its servants, agents, or contractors refuse or other rubbish outside its own area without the previous approval of the county council and the district council within whose area the refuse or rubbish is deposited, and subject to such conditions as may be prescribed by such councils; this restriction not to apply to ordinary stable manure sent direct to a farm for agricultural purposes. In the event of a county council or local authority refusing consent an appeal to be made to the Minister of Health, whose decision shall be final." This resolution, effective though it might be in dealing with the evil of indiscriminate dumping, does not, in our view, go so far to meet the existing need as the proposal embodied in Mr. Dawes's report—namely, that for the control of the scavenging arrangements of the London area there should be created an *ad hoc* authority representative of the large number of local sanitary authorities which in the aggregate go to the making of Greater London. The Committee of Inquiry at the Ministry of Health, which was appointed last March to review the whole subject, has had under consideration a proposal for the creation of one dumping ground to which the whole of London's refuse might be removed, sifted of paper, metal, rags, and other commercially useful materials, and then destroyed. For this scheme it is claimed that out of the millions of tons of refuse collected from London each year, not even the dust would be left. The work of the Committee of Inquiry has to some extent been held up through the death of its chairman, Sir John Gatti, but in view of the Minister of Health's pronouncement before the Metropolitan Mayors Association we may hope that appropriate action will be taken without further delay.

A MEDICAL SERVICE FOR CANCER PATIENTS.

A policy that endeavours to establish in the public mind the conviction that cancer, if recognized in an early stage, can be treated with a large prospect of success, necessarily implies the provision of adequate machinery for the diagnosis and treatment of this dread disease. The public is being urged to bring its suspicions and fears and discoveries promptly to medical examination, and these exhortations, reinforced as they now are by the suggestion that curative means other than surgical are available, are certain to have some, and probably an increasing, measure of success. The question naturally arises, therefore, whether when this response is secured the patient can count with certainty upon the skill and experience necessary both to decide the diagnostic issue and to provide the appropriate therapeutic measures. It is something to the good that the chance of early recognition and treatment should be afforded. But the more fully the public provide this chance the more urgent and weighty is the demand that the capacity to utilize it shall be at hand. To arouse and educate the public may be the first step, but, if a full advance is to follow, an efficient medical service is obviously essential. An improved procedure on the one side plainly asks for full competence on the other, and there are some not uninfluential voices which contend that more pressing than a campaign of popular education is the provision of more adequate facilities for diagnosis and treatment.

It is the position here defined that, some two years ago, led the American Society for the Control of Cancer to appoint a committee to review the existing situation and to report on the best methods of improving the medical services available to the cancer patient. The report of the committee (Dr. James Ewing, Dr. Robert B. Greenough, and Dr. John C. A. Gerster) has now been issued,[1] and it certainly calls for careful study. It is based upon personal investigations pursued on both sides of the Atlantic, and on discussions in which many experts have taken a share. No one will question the thoroughness of the inquiry or the courage of the conclusions. Possibly some of the developments proposed may be regarded as beyond practical attainment either on financial or on scientific grounds. High aim, however, is hardly a reproach, and especially may such an ambition be encouraged when an attempt is made to deal effectively with a disease which the authors describe as "the most important, economically, of all the causes of death."

The dominant note in the American report is the proposition that the care of cancer patients requires special training, and the word "care" is used in its broadest possible sense. Thus, while allowing that the family physician is the "key man" in cancer control, the authors of the report contend that general practice rarely affords the experience necessary to enable an early and confident diagnosis to be made, and that the special function of the family physician is to be on the alert and to refer any suspicious fact to a suitable authority. Similarly, the private surgeon, it is argued, though individual exceptions exist, is not generally equipped to deal efficiently with cases of cancer; and, still further, a plea is advanced for the organization, even in general hospitals, of a "tumour clinic" as a special department to which all the tumour patients should be referred. Applying the same principle, the report calls for pathologists able not only to make an accurate histologic diagnosis, but also "to determine the clinical type of the disease" and, so far as possible, "the grade of malignancy and radiosensitivity," and the opinion is expressed that "defects in this field form one of the most serious obstacles to the successful treatment of cancer." It may be assumed that this critical examination of the existing state of affairs is based mainly on facts observed in the United States, but the assertion is added that in Europe there is "uniform agreement that improvement in cancer service must precede any substantial progress in cancer control."

The practical proposals made in the report for the improvement of the cancer service aim at concentration, organization, and specialization. The central feature in the scheme is a limited number of cancer institutes, each equipped for all forms of treatment, including an adequate supply of radium, and provided with a staff which should include a general medical director and experts in surgery, radiology, physics, chemistry, and biology. Here not only clinical practice, but also research and teaching, are to be cultivated, and the institute should be a source of help and a court of appeal for the district in which it is situated. Cancer hospitals are to be encouraged, but should be affiliated each with a cancer institute, and no hesitation, it is argued, should be felt in enlisting municipal or State aid, though independent organizations or university affiliations are regarded as preferable. It is a pleasing feature of the report that its authors have never been led to consider their subject as one dealing merely with the cold hard facts of pathology and administration. Everywhere, it is urged, provision ought to be made for the full recognition of the economic status of the patient and for the therapeutic and social help of sufferers who are beyond the reach of any existing curative methods.

In these proposals it is not pretended that there is anything particularly original, and some of them, in view of recent developments, may be regarded as almost inevitable. In principle they are widely recognized in this country, and a good deal of actual practice is in harmony with them, though the necessary facilities are not ready to hand in districts remote from large centres. Probably the one most likely to be disputed is the proposal to organize a specialized "tumour clinic" in connexion with the service of each general hospital. Yet it is certain that the surgeon, the radiologist, the pathologist, and the experts in radium and x-ray therapy must establish mutual relations if the new and growing knowledge of the therapeutics of cancer is to secure for the patient all the advantages of modern research and practice. And more than a sympathetic word may certainly be allowed to the suggestion that conferences should be arranged between practitioners who deal with cancer as it appears in different regions of the body. Specialization, though inevitable, doubtless has its dangers, and the best way to guard against these is to neutralize isolation by communion on a common platform. Any development in organization and administration that is likely to increase knowledge and succour humanity ought, of course, to be promoted, and efforts in this direction may reasonably be commended to the public, for increased efficiency demands increased expense. Yet no multiplication of machinery is of value in the absence of early diagnosis, and here both the individual patient and the family practitioner are immediately concerned; if one must provide the opportunity the other must be ready to utilize it, and this well-worn lesson is not the least important word in the American report here briefly surveyed.

THE HARVEIAN FESTIVAL IN LONDON.

THE annual Harveian Commemoration at the Royal College of Physicians of London was celebrated on St. Luke's Day (October 18th) in the usual manner. In the afternoon the Harveian Oration was delivered at the College by Sir Wilmot Herringham, consulting physician to St. Bartholomew's Hospital. The Oration was historical in scope, being mainly concerned with the life and character of William Harvey and his relation to his contemporaries and to the times in which he lived. In developing his theme Sir Wilmot Herringham observed that in order to understand the England of Harvey it was necessary to imagine a society to which science was unknown, for in Harvey's time the few sciences that existed were but little removed from magic. After the Oration the President, Sir John Rose Bradford, presented the Bisset Hawkins Medal to Dr. Edward Mellanby, F.R.S., professor of pharmacology in the University of Sheffield. This medal is awarded triennially to a British medical practitioner who has performed work in advancing sanitary science or in promoting public health which, in the opinion of the College, deserves special recognition. The Baly Medal, awarded every alternate year to the person who shall be deemed to have most distinguished himself in the science of physiology, especially during the two years immediately preceding the award, was presented to Dr. E. D. Adrian, F.R.S., university lecturer in physiology at Cambridge. In the evening the customary dinner was held in the College in accordance with the injunction of Harvey: "Once every year there shall be a general Feast kept within the said College for all the Fellows that shall please to come." It was attended by a large number of Fellows, and many distinguished guests were entertained, including the Right Hon. Arthur Greenwood, Minister of Health, Lord Dawson of Penn, Mr. Justice Eve, Lord Gorell, Lord Riddell, Mr. V. Warren Low, Vice-President of the Royal College of Surgeons, the Rev. Chancellor S. G. Ponsonby, Sir Reginald Blomfield, R.A., Sir Percy Mackinnon, Sir Walter Fletcher, Secretary of the Medical Research Council, the Master of the Society of Apothecaries, and the Editors of the *British Medical Journal* and the *Lancet*. After the memory of William Harvey had been toasted in silence, the health of "The Guests" was proposed by the President and responded to by Mr. Arthur Greenwood and Mr. Justice Eve. Replying to the toast of "The Harveian Orator," proposed by the Senior Censor, Dr. Robert Hutchison, Sir Wilmot Herringham said that some excuse might be needed for a gossipy Oration, but after all "bottled gossip is the foundation of history." After dinner the library was visited, where the Harveian Librarian, Dr. Arnold Chaplin, had put on view a number of valuable books and MSS. possessed by the College.

PATHS OF INFECTION FROM THE NASAL CAVITIES TO THE BRAIN.

THE Committee on Vaccination, appointed in 1925 by the Minister of Health in conjunction with the Medical Research Council, includes in its terms of reference authority to inquire into "the practical methods which are available in the light of modern knowledge to diminish or remove any risks which may result from vaccination," and to report on these from time to time. This committee, it will be recalled, reported in 1928 that, while the risks attending vaccination remained substantially the same after the passing of the Vaccination Act and Order of 1898 as they were before, there appeared in 1923 on the death certificates of certain recently vaccinated children terms which suggested the occurrence of a disturbance of the central nervous system other than convulsions; and furthermore that, though the occasional occurrence of nervous symptoms following vaccinia was as old as the practice of vaccination itself, until recently nervous complications did not appear to have been recorded as concerned in bringing about a fatal issue. In the course of its inquiry into the nature and origin of these nervous manifestations the committee formed the opinion that for the solution of the specific problems with which it was concerned—indeed, for the study of acute nervous diseases in general—it was important to gain a knowledge of the channels by which infection might pass from the nasal cavities into the brain. Professor W. E. le Gros Clark, who, on the committee's recommendation, undertook a study of this aspect of the pathology of post-vaccinal encephalitis, has now submitted a report,[1] in which he describes the technique and results of his investigations, and discusses the extent to which the conclusions he has derived from them may be applied to man. Earlier researches have demonstrated the existence of abundant connexions between the subarachnoid space and the extracranial tissues by means of the perineural spaces of the cranial nerves, especially of the olfactory nerves. There is known to exist, therefore, a potential route along which infection may pass to the brain from the tissue spaces of the nasal submucosa. In order to demonstrate the actual path along which such an infection might travel, and at the same time to test the possible existence of a route of connexion by way of emissary vessels, lymphatics, and so forth, Professor le Gros Clark tried to find some appropriate solution or suspension of particulate matter whose passage from the nasal to the intracranial cavity of the experimental animal—in this case the rabbit—could be clearly demonstrated by macroscopic or microscopic methods. Positive results were obtained by dropping into the nasal cavities a solution of potassium ferrocyanide and iron ammonium citrate, which, it was found, was very rapidly absorbed by the nasal mucous membrane, reaching the surface of the brain within one hour. Absorption took place mainly through the olfactory submucosa, and only slightly through the submucosa of the respiratory region, a difference which may well be correlated with the special properties of the olfactory mucosa by which its sensory epithelium is brought into intimate contact with odoriferous substances of widely differing chemical composition. In this connexion Professor le Gros Clark cites the investigations of Lowndes Yates,[2] who, in a study of thirty-four cases of encephalitis lethargica, found evidence of nasal infection accompanied by well-marked ciliary paralysis and increased absorptive power in the mucosa—the latter probably being a factor which permitted the entrance of a filter-passing virus. In his own experiments Professor le Gros Clark found that the solution reached the subarachnoid spaces by way of the perineural sheaths of the olfactory nerves, the evidence indicating that the spaces of these sheaths were continuous above with the subarachnoid spaces and extended peripherally along the peripheral fibres of the olfactory nerves to the olfactory sensory epithelium. Although, however, perineural sheath spaces provided the main route by which the absorbed fluid reached the surface of the brain, there is some evidence that material may also pass to the intracranial cavity (but not directly into the subarachnoid space) by way of blood vessels piercing the cribriform plate in company with the olfactory nerves. No support was afforded for the supposition that the subarachnoid space is in direct communication with the lymphatic vessels of the nasal mucosa. In discussing the practical application of his investigation the author points out that the anatomical features of the nasal cavities and the region of the cribriform plate in man correspond closely with those of other mammals, including

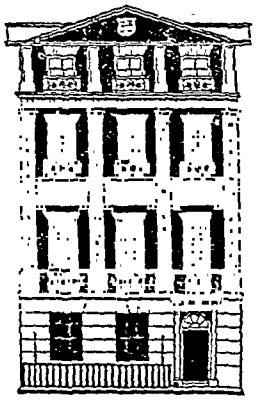
[1] Reports on Public Health and Medical Subjects. No. 54. Report of the Committee on Vaccination on an Anatomical Investigation into the Routes by which Infection may pass from the Nasal Cavities into the Brain. By W. E. le Gros Clark, D.Sc., F.R.C.S. Ministry of Health. 1929. Price 1s.

[2] The Condition of the Accessory Sinuses in Encephalitis Lethargica, *Journal of Laryngology*, vol. 40, 1925.

the rabbit, and suggests, therefore, that the conclusions derived from his experiments may safely be applied to man, with the reservation that in man the rate of absorption from the mucous surface may not necessarily be the same as in the rabbit.

THE LANCET'S NEW HOME.

During the past few days the editorial and publishing offices of the *Lancet* have been transferred from 1, Bedford Street, and 423, Strand, to the delightful house known as 7, Adam Street, Adelphi, whose freehold has been purchased by the proprietors. The move is a short one, for the buildings are only a hundred yards apart. Throughout its long history the editorial office of the *Lancet* has been in or very near the Strand, and our contemporary, in changing its quarters, has thus been able to maintain an unbroken tradition. From its first issue in 1823 until 1847 the paper was edited from a house in Norfolk Street, where Thomas Wakley, the founder, was engaged in private practice. In 1847 Wakley acquired the lease of the familiar building at the corner of Bedford Street, and from that time until 1921 the printing office was on the same premises. No. 7, Adam Street, stands in the middle of the eastern boundary of the famous block of buildings erected on the north bank of the Thames by Robert Adam and his brothers, John, James, and William, their joint authorship appearing in the word Adelphi—ἀδελφοί. The construction upon vaulted arches of these symmetrical streets was begun in 1773. The names of the two younger brothers have disappeared from their streets, and the connecting passage between the Strand and the Adelphi, at the north-west corner of the quadrangle, is now named Durham-house Street, in commemoration of the fact that nearly the whole area was once occupied by the town house of the bishops of Durham. The accompanying illustration shows the *Lancet's* new home as seen from the end of John Street. An informal house-warming party was held there on the evening of Wednesday, October 16th, when a large number of friends were received by the Editor and Lady Sprigge in the editorial room on the first floor, and afterwards had an opportunity of admiring the way in which Mr. Graham Dawbarn has carried out the work of *reconstruction*.



PURIFICATION OF SWIMMING-BATH WATER.

The practice of sterilizing and filtering the water in public swimming baths is gradually increasing. Up to 1912 in London only two of the metropolitan borough public swimming baths had filtration plants; now, out of a total of about a hundred public baths, at least forty-five have been fitted with them. Although in the provinces the increase has not been proportionately great, nevertheless progress has been made in this direction. The process is seen in its simplest form at an open-air bath such as that provided by the Harrow Urban District Council, where throughout the summer a continuous flow of water through the bath takes place, the contents of the bath being changed in the course of ten hours. The water, after flowing through a strainer to remove gross impurities, passes to the engine house and the sand filters. Prior to filtration a coagulant—alum—is introduced, and after filtration enough slaked lime is added to make the water slightly alkaline, and also the sterilizing agent—bleaching powder. Before re-entering the bath the water passes through a picturesque aerator of the cascade type, forming a series of small concentric waterfalls. The bleaching powder is added in such amount as to ensure the constant presence of chlorine in the bath water; at least 0.2 part per million must be present; the amount must not exceed 0.5 part, otherwise its presence will make itself felt by causing tingling and smarting of the conjunctivae. Experience of the open-air swimming pools under the control of the London County Council has shown that sterilization of swimming-bath water alone is not enough; it does not remove the slime. Filtration removes the turbidity (and any colour present in the water supplied) and gives the water a bright appearance, important because the look of the water is the only criterion by which the average bather can judge of its purity. Aeration adds to its freshness and sparkle. In a recent pamphlet on swimming-bath water purification[1] Mr. F. Wilkinson, the Willesden borough engineer, and Mr. F. J. Forty describe eight different filtration systems in use in this country. No attempt is made to estimate their relative efficiency; the authors consider that all the systems give good results. Some reference is made to further measures necessary to ensure the hygienic use of swimming baths. All costumes and towels hired out should be sterilized so as to ensure that they do not spread such diseases as ringworm; the common use of scrubbing brushes, the authors hold, spreads disease, and they should not be supplied for washing in the foot-bath or shower-bath, which every bather ought to use before entering the swimming bath. Children under 14 should be compelled to wash, and adults so advised by means of propaganda posters on the walls of the dressing boxes pointing out the unpleasantness and danger to other bathers if anyone enters the bath in a dirty or infectious condition. The bath superintendent should have authority to refuse admittance to the bath of anyone suffering from a running nose, the result of a heavy cold, as well as those presenting signs of skin disease.

The whole subject of the purification of the water of swimming baths has come into considerable prominence this week through the issue by the Ministry of Health of an interesting and exhaustive report by three of its officers, Messrs. E. A. Sandford Fawcett and H. T. Calvert, and Dr. J. Alison Glover.[2] Owing to the great increase in recent years in the provision and use of swimming baths, the Ministry recognizes the importance of taking measures to ensure that the water in these establishments is in a wholesome condition. Many improvements are practicable, often with a saving of cost, and the report (to which we shall refer in more detail on another occasion) contains practical suggestions to this end. With regard to the possibility of infection, the authors are satisfied that although other factors are important, transmission of disease by polluted bathing water does occur. Since pathogenic bacteria can live in dirty bath water for considerable periods, the water of swimming pools therefore requires constant and expert attention. Its bacteriological count should approximate to that of drinking water, and this standard of purity can best be maintained by a system of purification which combines efficient continuous filtration, with continuous and accurately controlled chlorination and aeration. While it is evident that the water in many public and private bathing pools is often deplorably dirty, and may thus be a source of danger to health, the authors find no evidence to support alarmist rumours suggesting that disease in epidemic form has its origin in swimming baths in this country.
